

REMARKS

Claims 25-31 are pending and there remain two outstanding issues. One is whether the Office may require restriction between nucleic acid sequences within a single claim. It is respectfully submitted that the Office may not properly restrict between the three nucleic acid sequences specified in each independent claim. The second is whether the claims have utility and whether the specification enables their use in accordance with 35 U.S.C. § 101 and 112, first paragraph. It is respectfully submitted that the claimed methods have well-established, specific, substantial and credible utilities and the specification teaches such uses.

Response to Restriction Requirements

In the Office action response filed January 31, 2003, the applicants elected the species of SEQ ID NO: 23 with traverse in response to the species election requirement set forth in paper no. 24 mailed December 31, 2002. In the Office action mailed May 6, 2003, the Office stated that the species election requirement was meant to be constructed as a restriction requirement and made the requirement final. The Office deemed for the first time in the Office action mailed May 6, 2003 that the election of SEQ ID NO: 23 was a requirement for restriction. Therefore, it is respectfully submitted that making the restriction requirement final was improper. Accordingly, it is respectfully requested that the Office withdraw the finality of the restriction requirement in the Office action mailed May 6, 2003 and consider the following remarks.

The claims are directed in part to processes for screening T-type calcium channel agonists and antagonists, where the channel is encoded by a nucleotide sequence which hybridizes to a nucleic acid comprising SEQ ID NO: 23, 25 or 27. It has long been held that the Office may not impose a restriction requirement on a single claim. *See In re Watkinson*, 14 USPQ.2d 1407 (Fed. Cir. 1990) citing *In re Weber*, 198 USPQ 328, 332 (CCPA 1978) and *In re Haas*, 198 USPQ 334, 336 (CCPA 1978). The courts have definitively ruled that the statute authorizing restriction practice (*i.e.* 35 U.S.C. § 121) provides no authority to impose a restriction requirement on a single claim, even if the claim presents multiple independently

patentable inventions. In these cases, the courts expressly ruled that there is no statutory basis for rejecting a claim for misjoinder, despite previous attempts by the Office to fashion such a rejection. As noted in *In re Weber*:

The discretionary power to limit one applicant to one invention is no excuse at all for refusing to examine a broad generic claim, no matter how broad, which means no matter how many independently patentable inventions may fall within it.

In re Weber at 334.

Alleging that a particular claim represents multiple “patentably distinct” inventions is a *de facto* rejection of the patentability of the claim because the claim cannot issue as drafted. In this regard the courts noted:

As a general proposition, an applicant has a right to have each claim examined on the merits. If an applicant submits a number of claims, it may well be that pursuant to a proper restriction requirement, those claims will be dispersed to a number of applications. Such action would not effect the rights of the applicant eventually to have each of the claims examined in the form he considers to best define his invention. If, however, a single claim is required to be divided up and presented in several applications, that claim will never be considered on the merits. The totality of the resulting fragmentary claims would not necessarily be the equivalent of the original claim. Further, since the subgenera would be defined by the examiner, rather than by the applicant, it is not inconceivable that a number of fragments would not be described in the specification.

See In re Weber, *supra*, emphasis added.

Instead of improperly imposing a restriction requirement on a given claim, the Office may limit initial examination to a “reasonable number” of species encompassed by the claim (*see* 37 C.F.R. § 1.146). This practice strikes an appropriate balance between administrative concerns of the Office and the clear constitutional and statutory rights of the inventor to claim an invention as it is contemplated. *See* MPEP at § 803.02; *In re Wolfrum*, 179 USPQ 620 (CCPA 1973); and *In re Kuehl*, 177 USPQ 250 (CCPA 1973). Unlike a restriction requirement, a species election does not preclude an applicant from pursuing the original form of a claim in subsequent

prosecution nor does it force an applicant to file multiple divisional applications that are incapable of capturing the intended scope of the application. Here, it should be clear that the added cost of filing and prosecuting multiple patent applications does not strike an appropriate balance between the administrative concerns of the Office and the applicants' statutory rights as inventors.

It also respectfully is submitted that there is no undue search burden on the Office when performing a database search for the pending claims. A search that covers one of the specified nucleic acid sequences should be broad enough to cover the two other related nucleic acid sequences. As one search should cover all three nucleotide sequences claimed, there should be no undue search burden on the Office. Accordingly, the applicants again provisionally elect claims directed to the use of the α_1 subunit species encoded by a nucleotide sequence that hybridizes to a nucleic acid comprising SEQ ID NO: 23, and request, respectfully, reconsideration of the restriction requirement.

The Claimed Subject Matter has a Well-Established Utility

The Office rejected the pending claims as the specification allegedly does not provide a specific, substantial or credible utility for the claimed subject matter. These rejections under 35 U.S.C. §§ 101 and 112, first paragraph respectfully are traversed. There are at least six features underscoring the utility of the claimed screening assays:

1. the α_1 subunits encoded by nucleotide sequences that hybridize to a nucleic acid comprising SEQ ID NO: 23, 25 or 27 are functional full-length subunits and the specification teaches a person of ordinary skill in the art how to use the specified α_1 subunits screening assays;
2. publications at the time the priority application was filed demonstrate T-type calcium channel assays had a well-established utility as they were useful for identifying compounds that treat diseases such as hypertension, stroke, epilepsy, heart disease and cancer;

3. a declaration submitted by Dr. Snutch, which must be considered by the Office, demonstrates the claimed screening methods are useful for identifying molecules that treat T-type calcium channel related diseases;

4. due to the facts delineated in items 1, 2 and 3, the screening assays have a well-established, specific, substantial and credible utility for identifying compounds useful for treating diseases enumerated in the specification;

5. little or no experimentation is required beyond the claimed processes to identify compounds that treat diseases listed in the specification; and

6. the Office already has allowed claims directed to T-type channels, proving that claims directed to their use have utility.

The following describes these features in greater detail.

First, the α_1 subunits encoded by nucleotide sequences that hybridize to a nucleic acid comprising SEQ ID NOs: 23, 25 or 27 form functional full-length calcium channels (*see e.g.*, specification on page 5, line 1, and page 24, lines 10-18). Although the properties of these channels may be modulated by co-expression of other subunits, the α_1 subunits alone are functional. The specification also clearly states on page 7 that the subunits are by themselves T-type calcium channels and teaches the person of ordinary skill in the art how to make recombinant cells utilized in the claimed methods (*see e.g.*, page 16, lines 19-27). The specification also teaches methods of using such receptors and recombinant cells in standard methods for screening agonists and antagonists. These well-established methods include whole patch clamp analysis, single channel analysis, ^{45}Ca uptake, fluorescence spectroscopy using calcium sensitive dyes such as FURA-2, and binding or displacement of radiolabeled ligands that interact with the calcium channel (*see e.g.*, page 22, lines 4-9). The Office recognized that the specification teaches these uses of the claimed processes as it admitted in the action mailed July 2, 2002 on page 7 that the specification teaches cell lines expressing α_1 subunits can be used

to evaluate the effects of pharmaceuticals and/or toxic substance on calcium channels. As the specification also teaches that the calcium channel subunit may be associated with human genetic diseases, the logical conclusion is the agonists and antagonists identified by the claimed screening assays are expected to be useful for treating these diseases. These diseases include including epilepsy, migraine, ataxia, schizophrenia, hypertension, arrhythmia, angina, depression, small lung carcinoma, Lambert-Eaton syndrome, and Parkinson's disease (*see* specification at page 9). Thus, the specification teaches the claimed processes are useful for identifying agonists and antagonists of T-type calcium channels and diseases associated with such channels.

Second, journal articles published before and at the time the priority application was filed in February of 1997 show that T-type calcium channel agonists were useful for treating a number of diseases set forth in the specification on page 9. These publications are exemplified by the abstracts attached herewith as Exhibits A through H. Abstracts in Exhibits A, B, C, D, E and F show the utility of the T-type calcium channel antagonist mibefradil for treating hypertension, heart disease, and stroke. The abstract in Exhibit G shows the utility of T-type calcium channel blockers nickel and amiloride for affecting the pathogenesis of insulinoma tumor cells. The abstract in Exhibit H shows the utility of the T-type calcium channel blocker zonisamide for treating epileptic seizures. Thus, the utility of T-type calcium channel screening assays for identifying therapeutic molecules was well-established before the priority application was filed.

Third, a compound that binds to one T-type calcium channel binds to all T-type calcium channels. Therefore a compound that treats a disease by binding one T-type channel will bind another T-type calcium channel and exert an effect due to the sequence homology between these channels. As it is well-established there are known T-type calcium channel antagonists useful for treating diseases listed in the specification, the claimed methods have utility for identifying therapeutic molecules. These facts are set forth in the declaration of Dr. Terrence Snutch executed July 10, 2001 and attached herewith as Exhibit I. The Office must consider the factual

analysis by Dr. Snutch as required by the utility examination guidelines (*Official Gazette*, January 30, 2001):

Office personnel are reminded that they must treat as true a statement of fact made by an applicant in relation to an asserted utility, unless countervailing evidence can be provided that shows that one of ordinary skill in the art would have a legitimate basis to doubt the credibility of such a statement. Similarly, Office personnel must accept an opinion from a qualified expert that is based upon relevant facts whose accuracy is not being questioned; it is improper to disregard the opinion solely because of a disagreement over the significance or meaning of the facts offered.

Because there is no evidence on the record refuting these facts, they must be considered as being true. Thus, the link between the claimed screening assays and the utility of agonists identified by the assays for treating T-type channel-associated diseases is clear.

Fourth, the claimed screening assays have a well-established, specific, substantial and credible utility. The utility is specific because the claimed screening assays are useful for identifying agonists and antagonists of the specified α_1 subunits. The utility is substantial as the agonists and antagonists identified by the screening methods have the real world use of treating diseases specified on page 9 of the specification. The utility is credible because the applicants have generated recombinant cells according to the claimed specification and have screened multiple molecules that act as agonists or antagonists of the α_1 T-subunits (a declaration demonstrating such experiments can be provided to the Office if required). The utility also is credible because the publications submitted in Exhibits A through H demonstrate the usefulness of particular T-type calcium channel agonists for treating diseases. Further, the utility of the claimed screening methods is well-established as evidenced by the state of the art before the filing date of the present patent application. For example, the patch clamp assays and radiolabel ligand assays referenced in the specification on page 22 were well-known in the art as of 1992. See e.g., Williams *et al.*, *Science* 257: 389-395 (1992) and Williams *et al.*, *Neuron*: 71-84 (1992), attached herewith as Exhibits J and K, respectively. Also, the publications in Exhibits A through H show the utility of T-type calcium channel screening assays for identifying agonists useful

from treating certain diseases. Accordingly, the claimed processes have a well-established, specific, substantial and credible utility.

Fifth, the claimed processes require little if no further experimentation for identifying agonists and antagonists useful for treating T-type channel-associated diseases. This feature is highlighted in the Snutch declaration discussed above (Exhibit I) in by journal articles published at the time and before the priority application was filed in 1997 (Exhibits A through H). As the use of the specified α_1 subunits in the claimed screening methods directly identify compounds useful for treating the diseases set forth in the specification, the claimed subject matter is not merely a hunting license as compared to the technology at issue in *Brenner v. Manson*. Also, there is no requirement to determine whether new agonists and antagonists identified by the claimed assays in fact treat a disease *in vivo* in accordance with *In re Brana*, 34 USPQ.2d 1436 (Fed. Cir. 1995). Accordingly, there is little if no further experimentation required to ascertain whether the agonists or antagonists identified by the claimed assays are useful for treating diseases associated with aberrations in α_1 subunits.

Sixth, the Office appears to have ignored the precedence of at least two patents have issued directed to nucleotide sequences encoding T-type calcium channels. These patent are U.S. Patent Nos. 6,358,706 and 6,309,858, attached herewith as Exhibits L and M, respectively. Based on the issuance of these patents the T-type calcium channels clearly are useful as presently claimed. Specifically, they are useful for identifying agonists and antagonists of calcium channel activity which in turn are useful for treating a number of conditions. These utilities are exactly the same as those stated by the patentees in these issued patents. *See e.g.*, columns 6, lines 33-50 in the '706 patent and column 19, lines 53-57 of the '858 patent. In addition, the Office has issued an entire litany of patents with respect to N-type calcium ion channels based on the same logic that applicants have been asserting in the present application. For example, U.S. Patent No. 6,096,514; U.S. Patent No. 6,090,626; U.S. Patent No. 6,013,474; and U.S. Patent No. 5,876,958 issued with the same requisite utility established for the presently claimed screening assays.

Accordingly, the claimed processes have a well-established, specific, substantial, credible and utilities as taught in the specification. As such, the applicants respectfully request that the Office withdraw the rejections under 35 U.S.C. §§ 101 and 112, first paragraph.

CONCLUSION

Given that the Office switched the species election requirement to a restriction requirement in the previous Office action, the applicants respectfully request that the Office consider the arguments set forth herein which demonstrate that the requirement for restriction is improper. The applicants also respectfully submit that the claimed screening methods have a specific, substantial, credible and well-established utility, and therefore, it is respectfully requested that the Office withdraw the rejections under 35 U.S.C. §§ 101 and 112, first paragraph.

In the unlikely event that the transmittal letter is separated from this document and the Patent Office determines that an extension and/or other relief is required, applicants petition for any required relief including extensions of time and authorize the Assistant Commissioner to charge the cost of such petitions and/or other fees due in connection with the filing of this document to **Deposit Account No. 03-1952** referencing docket No. 381092000720.

Respectfully submitted,

The antihypertensive efficacy of the novel calcium antagonist mibefradil in comparison with nifedipine GITS in moderate to severe hypertensives with ambulatory hypertension.

Lacourciere Y, Poirier L, Lefebvre J, Archambault F, Dalle Ave S, Ward C, Lindberg E.

Hypertension Unit, le Centre Hospitalier de l'Universite Laval, Saint-Foy, Quebec, Canada.

Mibefradil is a novel calcium antagonist that blocks selectively the T-type calcium channels. In this double-blind forced titration study design we compared the effects of mibefradil 50, 100, and 150 mg and nifedipine GITS 30, 60, and 90 mg monotherapies or combined with lisinopril 20 mg in 71 moderate to severe hypertensives (59 men and 12 women) with confirmed ambulatory hypertension. An incremental dose-response effect was observed both in clinic and ambulatory blood pressure parameters during treatment with mibefradil and nifedipine GITS alone and combined with lisinopril. At maximal dosage, patients treated with mibefradil experienced a greater ($P < .05$) reduction in clinic and ambulatory diastolic blood pressures as well as a greater response rate (86% v 69%). Trough:peak ratios for systolic and diastolic blood pressures were $> 90\%$ at each dose level. Significant decrease in baseline heart rate was observed with mibefradil 150 mg alone or combined with lisinopril, but no patients experienced clinically significant atrioventricular conduction abnormalities. Adverse events related to vasodilation were more prevalent in the nifedipine GITS group. Consequently, the results of the present study demonstrate that the novel calcium channel blocker mibefradil, either alone or in combination with lisinopril, is effective in reducing clinic and 24-h blood pressures while decreasing heart rate and is well tolerated in patients with moderate to severe hypertension.

Evaluating the safety of mibefradil, a selective T-type calcium antagonist, in patients with chronic congestive heart failure.

van der Vring JA, Bernink PJ, van der Wall EE, van Velhuisen DJ, Braun S, Kobrin I.

Martini Ziekenhuis, Groningen, The Netherlands.

Mibefradil is a novel calcium antagonist belonging to a new chemical class of benzimidazolyl-substituted tetraline derivatives. The safety of mibefradil in patients with mild-to-moderate chronic congestive heart failure (CHF) due to coronary heart disease was assessed in a randomized, double-masked, placebo-controlled, multiple-ascending-dose trial in 45 patients. Patients were assigned to receive one of five dose levels (6.25, 12.5, 25, 50, or 100 mg/d) of mibefradil or placebo according to a randomization list. If safety variables remained stable, the subsequent group of patients was randomized to the next higher dose. The safety variables assessed included New York Heart Association class, vital signs, and ejection fraction. Patients were evaluated at baseline and day 8 of the dosing period. Mibefradil did not worsen clinical or cardiac variables. Approximately 23.3% (7 of 30) of the mibefradil-treated patients reported one or more adverse events compared with 13.3% (2 of 15) of the placebo group. The incidence of adverse events was not dose dependent. In summary, short-term oral dosing of mibefradil did not worsen measures of cardiac function in 30 patients with mild-to-moderate CHF.

Hemodynamic and cardiac effects of the selective T-type and L-type calcium channel blocking agent mibefradil in patients with varying degrees of left ventricular systolic dysfunction.

Rousseau MF, Hayashida W, van Eyll C, Hess OM, Benedict CR, Ahn S, Chapelle F, Kobrin I, Pouleur H.

Division of Cardiology, University of Louvain, Brussels, Belgium.

OBJECTIVES: This study sought to assess the hemodynamic and cardiac effects of two dose levels of mibefradil in patients with varying degrees of ischemic left ventricular dysfunction. **BACKGROUND:** Mibefradil is a new, selective T-type and L-type calcium channel blocking agent. Because L-type channel blockade may depress myocardial performance, an invasive hemodynamic study was performed to assess the safety of this agent. **METHODS:** We performed an open label study, examining the effects of two intravenous doses of mibefradil, selected to produce plasma levels comparable to those measured after oral administration of 50 mg (dose 1: 400 ng/ml) or 100 mg (dose 2: 800 ng/ml) of the drug. Variables studied included the indexes of left ventricular function and neurohormone levels. Patients were stratified according to ejection fraction (EF) (\geq or $<$ 40%, $n = 26$; $n = 24$) and the presence ($n = 15$) or absence ($n = 35$) of heart failure. **RESULTS:** In patients with preserved systolic function, dose 1 had no clinically significant hemodynamic effects, but dose 2 decreased mean aortic pressure and systemic vascular resistance (-8.5 mm Hg, -12% , both $p < 0.01$) and also reduced end-systolic stress and volume, thus improving EF (52% to 58%, $p < 0.01$). Heart rate tended to decrease. In patients with depressed EF, heart rate decreased significantly with both doses. The effects of dose 1 mimicked those observed after dose 2 in patients with preserved EF. Dose 2 (plasma levels $1,052 \pm 284$ ng/ml) still decreased left ventricular systolic wall stress and improved EF (24.0% to 28.5%, $p < 0.05$) but also significantly depressed the maximal first derivative of left ventricular pressure. Examination of individual pressure-volume loops in two patients with heart failure showed a clear rightward shift of the loop despite a decrease in systolic pressure, suggesting negative inotropy. Neurohormone levels were unchanged at both dose levels and in all subgroups. **CONCLUSIONS:** Intravenous mibefradil was well tolerated and produced an overall favorable cardiovascular response. However, high plasma concentrations might produce myocardial depression in patients with heart failure, and caution should be exerted in this setting.

Effects of mibefradil on large and small coronary arteries in conscious dogs: role of vascular endothelium.

Karila-Cohen D, Dubois-Rande JL, Giudicelli JF, Berdeaux A.

Department de Pharmacologie, Faculte de Medecine Paris-Sud, France.

The systemic and coronary hemodynamic effects of mibefradil, a "nondihydropyridine" calcium antagonist acting on both L- and T-type calcium channels, were investigated in chronically instrumented conscious dogs before and after local endothelium removal of the circumflex coronary artery by angioplasty. After intravenous infusion, mibefradil (0.2 mg kg⁻¹ min⁻¹) decreased mean arterial blood pressure (MAP; -15 +/- 1%), increased heart rate (HR; 58 +/- 9%), and coronary blood flow (CBF; 103 +/- 14%) (all p < 0.05). Before endothelium removal, mibefradil increased the diameter of the left circumflex epicardial coronary artery (LCX) by 7.8 +/- 1.2% from 3,006 +/- 219 microns, but this dilatory effect was significantly reduced by 69% (p < 0.001) and 45% (p < 0.01), 3 and 21 days after endothelium removal, respectively. Mibefradil also reduced by 46% (p < 0.01) the potent coronary constrictor effect of ergonovine (300 micrograms intravenous bolus). These results demonstrate that mibefradil is a potent dilator of large and small coronary arteries in conscious dogs and that approximately 30% of its dilatory effect on large coronary artery is endothelium-independent. In addition, mibefradil prevents ergonovine-induced epicardial coronary constriction.

Mibefradil, a selective calcium T-channel blocker, in stroke-prone spontaneously hypertensive rats.

Vacher E, Richer C, Fornes P, Clozel JP, Giudicelli.

Departement de Pharmacologie, Faculte de Medecine Paris-Sud, Le Kremlin-Bicetre, France.

Several types of antihypertensive agents, including calcium antagonists, have been reported to prevent stroke and prolong survival in stroke-prone spontaneously hypertensive rats (SHR-SP). We investigated whether mibefradil, a new calcium antagonist acting selectively at the level of T-type calcium channels, would be able to (a) limit or prevent the structural and functional alterations that develop in the cerebral arteries of SHR-SP before stroke and (b) suppress stroke and prolong survival. Mibefradil (30 mg/kg/day) was given orally to young salt-loaded SHR-SP from age 5 weeks to age 20 weeks. Blood pressure (BP) (in conscious animals), diuresis, and proteinuria were determined weekly. After 10/12 weeks of treatment, middle cerebral arteries and aortas were removed from randomly selected control and treated SHR-SP. Aortic media thickness and collagen density were evaluated by histomorphometry. Middle cerebral arteries were mounted in a myograph for wall thickness determination and isometric tension recordings. Mibefradil completely prevented stroke and mortality, significantly limited the increase in BP, and opposed the increases in diuresis and proteinuria observed in controls. Simultaneously, mibefradil abolished vascular fibrinoid necrosis formation in the brain and reduced arterial thickening in the cerebral artery as well as in the aorta. The maximal contractile responses of the cerebral arteries to potassium chloride and serotonin were greater in mibefradil-treated animals than in controls, as were the endothelium-dependent relaxant responses. Mibefradil, chronically administered to young SHRSP in a dose that limits the development of hypertension not only prevents stroke and mortality but also affords protection against the vascular structural alterations which develop with age in these animals and preserves or improves the cerebral artery's smooth muscle and endothelial cell functions.

- Cardiovasc Drugs Ther. 1996 May;10(2):101-5.

Prevention of neointima formation by mibefradil after vascular injury in rats: comparison with ACE inhibition.

Schmitt R, Clozel JP, Iberg N, Buhler FR.

Pharma Division, F. Hoffmann-La Roche Ltd., Basel, Switzerland.

Cilazapril, an angiotensin-converting enzyme inhibitor, and mibefradil, a selective T-type voltage-operated calcium channel blocker, have been shown to prevent neointima formation after vascular injury. The goal of the present study was to evaluate the mechanism of action of both drugs. For this purpose, the influence of the renin angiotensin system on the effects of mibefradil (30 mg/kg po) and cilazapril (10 mg/kg po) on neointima formation after carotid injury were evaluated in normotensive rats (normal renin angiotensin system) and DOCA hypertensive rats (suppressed renin angiotensin system). In addition, in order to differentiate an effect on cell migration or cell proliferation, both drugs were given either before or after the smooth muscle migration phase. Finally, cilazapril and mibefradil were given in combination. In normotensive rats, mibefradil and cilazapril decreased neointima formation, resulting in neointima/media ratios of 38% ($p < 0.05$) and 53% ($p < 0.01$), respectively. However, in DOCA hypertensive rats, mibefradil was active, with a reduction of the neointima/media ratio by 63% ($p < 0.001$), whereas cilazapril reduced it only slightly (19%) and not significantly. In addition, cilazapril was active only when treatment started before the migration phase (63%, reduction in neointima/media ratio, $p < 0.001$) but not when started thereafter (13% reduction in neointima/media ratio, n.s.). In contrast, treatment with mibefradil was also active when started after the migration phase (51% reduction in neointima/media ratio, $p < 0.001$ when treatment started 1 day before balloon injury and 41%, $p < 0.01$ when treatment started 5 days after balloon injury). The combination of both drugs was additive (67% reduction in neointima/media ratio, $p < 0.001$ vs. control). These experiments clearly show that mibefradil and cilazapril have a different mechanism of action after vascular injury. Mibefradil most likely prevents the proliferation of smooth muscle cells. In contrast, cilazapril most likely inhibits the migration of smooth muscle cells. These two different mechanisms of action explain why the effects of both drugs are additive.

Abnormally expressed low-voltage-activated calcium channels in beta-cells from NOD mice and a related clonal cell line.

Wang L, Bhattacharjee A, Fu J, Li M.

Department of Pharmacology, University of South Alabama, College of Medicine, Mobile 36688, USA.

A macroscopic low-voltage-activated (LVA) inward current was found in pancreatic beta-cells isolated from NOD mice. However, this current was not present in nondiabetic prone mouse (e.g., Swiss-Webster) pancreatic beta-cells. We performed pharmacological analyses on this current in NOD insulinoma tumor cells (NIT-1). This cell line was developed from pancreatic beta-cells of a transgenic NOD mouse. The sodium-channel blocker, tetrodotoxin (TTX; 2 micromol/l) had no effect on this LVA current. The amplitudes of currents elicited by a -20 mV test pulse retained similarity when the extracellular sodium concentration was increased from 0 to 115 mmol/l; when the extracellular calcium concentration was decreased from 10 to 2 mmol/l, there was an approximate 50% reduction of this current elicited by a -30 mV test pulse. Neither the L-type calcium-channel blocker, nifedipine (3 micromol/l), nor the N-type calcium-channel blocker, omega-CgTx-GVIA (1 micromol/l), at -30 mV produced an appreciable effect. The T-type calcium-channel blockers, nickel (3 micromol/l) and amiloride (250 micromol/l), effectively reduced the peak of this current. In 2 mmol/l calcium external solution, the threshold of voltage-dependent activation of this calcium current was approximately -65 mV, and the peak current occurred at -20 mV. Half-maximum steady-state inactivation was around -43 mV. The mean time constant of slow deactivating tail currents generated by a preceding 20 mV pulse was 2.53 ms. The intracellular free calcium concentration was two- to threefold higher in NOD mouse pancreatic beta-cells compared with Swiss-Webster pancreatic beta-cells. We concluded that there are LVA calcium channels abnormally expressed in NOD mouse beta-cells. This LVA calcium channel may be factorial to the high cytosolic free calcium concentration observed in these cells, and thereby may contribute to the pathogenesis of NOD mouse beta-cells.

Mechanisms of T-type calcium channel blockade by zonisamide.

Kito M, Maehara M, Watanabe K.

Department of Pediatrics, Minami Seikyo Hospital, Nagoya, Japan.

We investigated the effects of zonisamide, a new antiepileptic drug, on voltage-dependent T-type calcium current (ICa) in cultured neuroblastoma cells of human origin (NB-I). Zonisamide reduced T-type ICa in a concentration-dependent manner without evoking any change in its inactivation kinetics or voltage dependence of action. The mean percent reduction was $38.3 \pm 5.8\%$ at 50 μM . Further, zonisamide shifted the inactivation curve approximately 20 mV negative compared to the control. These resting blocking actions suggest that zonisamide shifts the channel population toward the inactivation state, allowing fewer channels to open during membrane depolarization. The blockade of T-type calcium channels by zonisamide could suppress an important component of inward current that underlies epileptiform cellular bursting, thereby inhibiting the spread of seizure activity.

DECLARATION OF DR. TERRANCE SNUTCH

Assistant Commissioner for Patents
Washington, D.C. 20231

Dear Sir:

I, Terrance Snutch, declare as follows:

1. I am a co-inventor of the subject matter claimed in the above-referenced application and have been practicing in the field of molecular biology, and specifically in the field of ion channels, for over 15 years. A copy of my *curriculum vitae* is attached hereto as Exhibit A. I have published many papers on the structure and function of calcium channels and am considered one of the leading researchers in this field.

2. The association of abnormal T-type calcium channel activity with specific conditions is well known in the art. Enclosed herewith are a number of documents which verify this. Abnormal T-type activity is associated with a number of cardiac conditions including

pacemaker activity (Hajiwara, *et al.*, *J. Physiol.* (1988) 395:233-253; cardiac hypertrophy (Nuss, *et al.*, *Circ. Res.* (1995) 73:777-782); and hypertension (Self, *et al.*, *J. Vasc. Res.* (1994) 31:359-366). Abnormal T-type calcium function is also associated with neurological diseases wherein neuronal bursts are abnormally fired causing spastic convulsions (Huguenard, *Ann. Rev. Physiol.* (1996) 58:329-348) and thus associated with epilepsy (Tsakiridou, *et al.*, *J. Neuro. Sci.* (1995) 15:3110-3117; Coulter, *et al.*, *Brit. J. Pharmacol.* (1990) 100:800-806). Abnormal function of the T-type calcium ion channel is also associated with impaired fertility because of its effect on hormone secretion (Rossier, *et al.*, *Endocrinology* (1966) 137:4817-4826; Arnoult, *et al.*, *Proc. Natl. Acad. Sci. USA* (1996) 93:13004-13009). Copies of these documents are attached hereto. Thus the conditions associated with abnormal T-calcium channel function are well established and agonists and antagonists of T-type calcium channels are useful in treating these conditions.

3. There are several T-type calcium channels found in a single individual which vary slightly in structure and demonstrably in terms of their distribution among various tissues. This, however, does not affect the usefulness of screening assays for agonists and antagonists. The particular T-type calcium channel involved in a particular condition may depend on its tissue distribution; for instance, T-type channels found in the nervous system are associated with epilepsy and neurological diseases in general where spastic convulsions are involved. However, it is not necessary to understand which particular T-type calcium channel is being used in a screen for compounds that would be useful in treating, for example, these convulsive conditions because of the similarity in the binding specificity of all T-type channels. In very simple terms, compounds which are found to inhibit or stimulate the activity of nervous T-type channels will also inhibit or stimulate the activity of T-type channels found in other tissues. Thus, any arbitrarily chosen T-type channel could be expressed in a cell line for use in screening assays to identify agonists or antagonists and the agonists or antagonists would be useful in treating the conditions associated with any T-type channel. As noted above, abnormal T-type activity is associated with a number of cardiac conditions, with hypertension, with neurological diseases involving spastic convulsions, and with impaired fertility. An agonist or antagonist identified with regard to any T-type channel would be useful in any and all of these conditions.

4. This pattern of similar binding activity among all T-type channels can be analogized to such a pattern among L-type channels. All of the T-type channels have similar

behaviors in that they activate at low membrane potential, have small single channel conductance, have negative steady state inactivation properties, and contribute to spike firing patterns and rhythmic bursting processes. Analogous to the T-type channel another type of channel linked by similar behaviors is the L-type. There are several α_1 subunits associated with various L-type channels - i.e., α_{1S} , α_{1C} , and α_{1D} and each is encoded by a distinct gene and exhibits a distinct distribution pattern. For example, α_{1S} is in skeletal muscle; α_{1C} is in neurons and cardiac and smooth muscle; and α_{1D} is found in neurons and endocrine cells. They can be discriminated from all other types of calcium channels by their common sensitivity to 1,4-dihydropyridines. Thus, any one of these genes could be used to generate an L-type calcium channel for use in a cell-based assay to identify interacting compounds. These interacting compounds bind to all L-type channels and thus are useful in treating conditions related to any one of them.

I declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further, that these statements are made with the knowledge that willful, false statements and the like so made are punishable by fine or imprisonment or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

Terrance Snutch

concentrations of L-Arg (5 to 100 mM) to muscles treated with L-NMMA and TNF- α resulted in a more pronounced negative inotropic effect than that seen with TNF- α alone [$19 \pm 4\%$ of baseline tension with TNF- α and L-Arg as compared to $59 \pm 7\%$ of baseline tension with TNF- α alone ($P < 0.01$, $n = 6$; Student's two-tailed t test)] (Fig. 4A). This suggests that L-Arg enhanced the negative inotropic effect of TNF- α by providing additional substrate for NO production. This effect was also greater than that seen with L-Arg (100 mM) alone ($31 \pm 6\%$ of baseline tension; $P < 0.01$, $n = 6$; Student's two-tailed t test). The addition of L-Arg (100 mM) to muscles treated with L-NMMA and IL-6 reduced tension to $35 \pm 3\%$ (Fig. 4B). The addition of L-Arg (100 mM) to muscles treated with L-NMMA and IL-2 reduced tension to $11 \pm 10\%$ of baseline (Fig. 4C). All of these inotropic effects were completely reversed within 30 min after the cytokines or other agents were washed away (Fig. 4, A through C). Removal of the endothelium did not alter the negative inotropic responses of the papillary muscles to cytokines (Fig. 4, A through C).

Cytokines increase the amount of NO in noncardiac tissues by inducing the transcription of an inducible NO synthase (13–16). The rapid onset and reversibility of the effects seen in this report argue against an effect requiring gene transcription. The negative inotropic effects of these cytokines in the papillary muscle preparation appear to result from enhanced activity of a constitutive NO synthase enzyme in the myocardium.

The observed inotropic effects of pro-inflammatory cytokines raise the possibility that they participate in reversible, postischemic myocardial depression ("stunning"). Myocardial stunning frequently occurs after cardiopulmonary bypass and may complicate successful recovery from cardiac surgery (5–9). We found elevated concentrations of IL-6 (1800 to 4000 U/ml) in bronchoalveolar fluid from patients after cardiopulmonary bypass (18). IL-6 also reversibly decreased tension generated by pectinate muscles removed from patients at the time of surgery (18). These preliminary observations in patients support the clinical relevance of our findings with the Syrian hamster papillary muscle preparation. Thus, the regulation of pro-inflammatory cytokines and myocardial NO synthase may provide new therapeutic strategies for the management of cardiac patients.

Structure and Functional Expression of an ω -Conotoxin-Sensitive Human N-Type Calcium Channel

Mark E. Williams, Paul F. Brust, Daniel H. Feldman, Saraswathi Patthi, Susan Simerson, Azarnoush Maroufi, Ann F. McCue, Gönül Veliçelebi, Steven B. Ellis, Michael M. Harpold*

N-type calcium channels are ω -conotoxin (ω -CgTx)-sensitive, voltage-dependent ion channels involved in the control of neurotransmitter release from neurons. Multiple subtypes of voltage-dependent calcium channel complexes exist, and it is the α_1 subunit of the complex that forms the pore through which calcium enters the cell. The primary structures of human neuronal calcium channel α_{1B} subunits were deduced by the characterization of overlapping complementary DNAs. Two forms (α_{1B-1} and α_{1B-2}) were identified in human neuroblastoma (IMR32) cells and in the central nervous system, but not in skeletal muscle or aorta tissues. The α_{1B-1} subunit directs the recombinant expression of N-type calcium channel activity when it is transiently co-expressed with human neuronal β_2 and $\alpha_{2\delta}$ subunits in mammalian HEK293 cells. The recombinant channel was irreversibly blocked by ω -CgTx but was insensitive to dihydropyridines. The $\alpha_{1B-1}\alpha_{2\delta}\beta_2$ -transfected cells displayed a single class of saturable, high-affinity (dissociation constant = 55 pM) ω -CgTx binding sites. Co-expression of the β_2 subunit was necessary for N-type channel activity, whereas the $\alpha_{2\delta}$ subunit appeared to modulate the expression of the channel. The heterogeneity of α_{1B} subunits, along with the heterogeneity of α_2 and β subunits, is consistent with multiple, biophysically distinct N-type calcium channels.

Voltage-dependent Ca^{2+} channels are multisubunit complexes through which extracellular Ca^{2+} enters excitable cells. In rabbit skeletal muscle, four tightly coupled subunits, α_1 , α_2 , β , and γ , make up the channel complex (1). The primary structure of each subunit has been determined and α_1 , α_2 , and β cDNAs have been used to characterize transcripts expressed in other tissues (2). The α_1 and β subunits are each encoded by a gene family, including at

least five distinct genes for α_1 subunits and three genes for β subunits (3–6). Primary transcripts of each of the α_1 genes, the α_2 gene, and two of the β genes have been shown to yield multiple, structurally distinct, subunits by means of differential processing (6–9). Expression studies have shown that the α_1 subunit forms the pore through which Ca^{2+} enters the cell (10, 11).

On the basis of biophysical and pharmacological characteristics, three subtypes of neuronal, high-voltage-activated Ca^{2+} channels (L-, N-, and P-type) have been proposed (2). These high-voltage-activated

Fig. 1. Alignment of α_1 subunit deduced amino acid sequences. The nucleotide sequences have been deposited in GenBank (accession numbers M94172 and M94173 for α_{1B-1} and α_{1B-2} , respectively). The number of the amino acid residue at the end of each line is given. Abbreviations for the amino acid residues are: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asn; P, Pro; Q, Gln; R, Arg; S, Ser; T, Thr; V, Val; W, Trp; and Y, Tyr. Identical residues at one position in at least two of the sequences are enclosed in boxes. Potential N-glycosylation (o), cyclic adenosine monophosphate (AMP)-dependent phosphorylation (<), and protein kinase C phosphorylation

(>) sites (36) are shown. (A) Alignment of functional, neuronal α_1 subunits; the amino acid sequences of the human neuronal Ca^{2+} channel α_{1B-1} (1B-1), the human neuronal α_{1D} (1D) (8), and the rabbit brain BI-2 (1A-2) (11) are shown. BI-2 is designated 1A-2 because it is a rabbit homolog of the rat brain class A gene (4). The numbering begins with the proposed initiating methionine. The putative transmembrane segments S1 through S6 in each of the repeats I through IV are shown (brackets). (B) Alignment of α_{1B-1} and α_{1B-2} sequences through the region of the insertion-deletion (21). The deduced amino acid sequence of the 187-nt insertion (α_{1B-1} nt 6490 to 6676; Gly²¹⁶⁴ to Gly²²²⁶) is shown.

subtypes are most readily distinguished pharmacologically. The neuronal L-type channel is dihydropyridine (DHP)-sensitive and, in some cases, reversibly blocked by ω -conotoxin (ω -CgTx) (12, 13), the N-type channel is DHP-insensitive and irreversibly blocked by ω -CgTx (14), and the P-type channel is both DHP- and ω -CgTx-insensitive but is sensitive to toxins in venom from funnel web spiders (15). Recently, recombinant expression of neuronal Ca^{2+} channels was used to identify a high-voltage-activated, DHP-sensitive Ca^{2+}

channel that was reversibly blocked by ω -CgTx (classified as an L-type channel) (8) and a DHP-, ω -CgTx-insensitive Ca^{2+} channel (possibly a P-type channel) (11). Co-expression of α_1 and β subunits is necessary for substantial functional expression of both Ca^{2+} channel subtypes, whereas addition of an α_2 subunit increases the magnitude of the functional response.

Much evidence indicates that DHP-insensitive N-type Ca^{2+} channels that are irreversibly blocked by ω -CgTx are responsible for the voltage-activated release of

neurotransmitters in many neurons (16). In addition, ω -CgTx binding sites have been localized to the frog neuromuscular presynaptic membrane (17) and to organized, single clusters coincident with synaptic contact sites in hippocampal neurons (18). Furthermore, ω -CgTx binding sites on the presynaptic membrane of the frog neuromuscular terminal align precisely with active zones where vesicular exocytosis of neurotransmitters occurs (16, 17). Finally, ω -CgTx irreversibly blocks Ca^{2+} currents recorded directly from presynaptic termi-

nals (19). We report here the complete amino acid sequence of a human neuronal α_1 subunit (designated α_{1B}) that mediates N-type voltage-dependent Ca^{2+} channel activity, which is irreversibly blocked by ω -CgTx when transiently co-expressed with the human neuronal α_{2b} and β_2 subunits (8) in human embryonic kidney (HEK) 293 cells. The transfected cells bind ω -CgTx with high affinity.

We previously reported the isolation of cDNAs that encode the α_1 subunit of the rabbit skeletal muscle DHP-sensitive, L-type Ca^{2+} channel (3). These cDNAs were used as probes to isolate overlapping cDNAs encoding a complete human neuronal α_{1B} subunit (20). The translation initiation site was assigned to the first in-frame methionine codon, and no upstream in-frame nonsense codon was identified (Fig. 1A). Two isoforms of α_{1B} , α_{1B-1} and α_{1B-2} , that differ at their COOH-termini were identified (Fig. 1B). The α_{1B-1} subunit is comprised of 2339 amino acids and yields a calculated molecular weight of 262,494, whereas the α_{1B-2} subunit is comprised of 2237 amino acids and yields a calculated molecular weight of 251,757. These isoforms were identified by polymerase chain reaction (PCR) analysis (21) and revealed a deletion that produces α_{1B-2} , which likely results from alternative selection of a splice acceptor. This insertion-deletion that produces different COOH-termini is similar to the processing of putative rabbit α_{1A} gene transcripts encoding the rabbit BI-1 and BI-2 isoforms that mediate DHP-, ω -CgTx-insensitive high-voltage-activated Ca^{2+} channel activity (11). The α_{1B} sequence is 94.5% identical to the previously reported 164-amino acid sequence deduced from a rat brain class B partial cDNA (4) and has the same transmembrane topology as described previously for other Ca^{2+} channel α_1 subunits (7).

The deduced amino acid sequences of two different neuronal α_1 subunits, the human α_{1D} (8) and the rabbit BI-2 (11), are shown aligned with the human α_{1B-1} sequence (Fig. 1A). The α_{1B-1} amino acid sequence is 64.1% and 43.0% identical to the BI-2 and α_{1D} sequences, respectively. The sequence identity is relatively well conserved through the four repeating domains, 72.6% and 50.7% for the α_{1B-1} /BI-2 and the α_{1B-1} / α_{1D} pairs, respectively. Both of the DHP-insensitive α_1 subunits, human neuronal α_{1B-1} and rabbit neuronal BI-2, have characteristic large putative cytoplasmic loops between the IIS6 and IIS1 transmembrane domains. PCR analysis performed on RNAs isolated from IMR32 cells and several human primary tissues with α_{1B-1} - and α_{1B-2} -specific oligonucleotides identified α_{1B-1} and α_{1B-2} transcripts in IMR32 cells and in each of the human

central nervous system (CNS) tissues tested, including hippocampus, habenula, and thalamus but not in human skeletal muscle or aorta tissues (22).

The transient expression of the human neuronal α_{1B-1} , α_{2b} , and β_2 (8) subunits was studied in HEK293 cells (23). Transfected cells were examined for inward Ba^{2+} currents (I_{Ba}) mediated by voltage-dependent Ca^{2+} channels (24). Cells cotransfected with the α_{1B-1} , α_{2b} , and β_2 cDNAs expressed high-voltage-activated Ca^{2+} channels (Fig. 2). I_{Ba} first appeared when the membrane was depolarized from a holding potential of -90 mV to -20 mV and peaked in magnitude at 10 mV. Thirty-nine of 95 cells (12 independent transfections) had I_{Ba} that ranged from 30 to 2700 pA, with a mean of 433 pA. The mean current density was 26 pA/pF, and the highest density was 150 pA/pF (25). The I_{Ba} typically increased by 2- to 20-fold during the first 5 min of recording. Repeated depolar-

izations during long recordings often revealed rundown of I_{Ba} usually not exceeding 20% within 10 min. I_{Ba} typically activated within 10 ms and inactivated with both a fast time constant ranging from 46 to 105 ms and a slow time constant ranging from 291 to 453 ms ($n = 3$). Inactivation showed a complex voltage dependence, such that I_{Ba} elicited at ≥ 20 mV inactivated more slowly than I_{Ba} elicited at lower test voltages, possibly a result of an increase in the magnitude of slow compared to fast inactivation components at higher test voltages.

Recombinant $\alpha_{1B-1}\alpha_{2b}\beta_2$ channels were sensitive to holding potential (Fig. 3). Steady-state inactivation of I_{Ba} , measured after a 30- to 60-s conditioning at various holding potentials, was approximately 50% at holding potentials between -60 and -70 mV and approximately 90% at -40 mV. Recovery of I_{Ba} from inactivation was usually incomplete, measuring 55 to 75% of the original magnitude within 1 min after the holding potential was returned to more negative potentials, possibly indicating some rundown or a slow recovery rate.

Recombinant $\alpha_{1B-1}\alpha_{2b}\beta_2$ channels were also blocked irreversibly by ω -CgTx concentrations ranging from 0.5 to 10 μM during the time scale of the experiments (Fig. 4). Application of 5 μM toxin ($n = 7$) blocked the activity completely within 2 min, and we observed no recovery of I_{Ba} after washing ω -CgTx from the bath for up to 15 min. Cd^{2+} blockage (50 μM) was rapid, complete, and reversible; the DHPs Bay K 8644 (1 μM ; $n = 4$) or nifedipine (5 μM ; $n = 3$) had no discernable effect.

Cells cotransfected with cDNAs encoding α_{1B-1} , α_{2b} , and β_2 subunits predominantly displayed a single class of saturable, high-affinity ω -CgTx binding sites (26) (Fig. 5). The determined dissociation constant (K_d) value (Fig. 5) was 54.6 ± 14.5 pM ($n = 4$). Cells transfected with the vector containing only β -galactosidase cDNA or $\alpha_{2b}\beta_2$ cDNA showed no specific binding. The binding capacity (B_{max}) of the $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells was $28,710 \pm 11,950$ sites per cell ($n = 4$).

These results demonstrate that $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells express high-voltage-activated, inactivating Ca^{2+} channel activity that is irreversibly blocked by ω -CgTx, insensitive to DHPs, and sensitive to holding potential. The activation and inactivation kinetics and voltage sensitivity of the channel formed in these cells are generally consistent with previous characterizations of neuronal N-type Ca^{2+} channels (27, 28). Furthermore, the K_d value determined for ω -CgTx binding is in agreement with previously reported values (29).

The binding characteristics of ω -CgTx to HEK293 cells transiently expressing various subunit combinations were determined

Fig. 2. Voltage dependence and kinetics of I_{Ba} expressed in HEK293 cells transfected with α_{1B-1} , α_{2b} , and β_2 cDNAs (23). (A) Family of currents evoked at test voltages from -30 to 60 mV, from a holding potential of -90 mV. (B) Peak current-voltage relations measured from the currents in (A).

Fig. 3. Holding potential sensitivity of I_{Ba} expressed in HEK293 cells transfected with α_{1B-1} , α_{2b} , and β_2 cDNAs (23). Peak current-voltage (I - V) relations measured from voltage steps delivered from different holding potentials (-90 mV, \square ; -70 mV, \circ ; -50 mV, Δ ; return to -90 mV, ∇).

from saturation binding analysis (Table 1). Each recombinant cell type displayed a single class of binding sites similar to the $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells, with K_d values ranging from 38.8 ± 13.1 pM to 76.1 ± 15.5 pM. The binding affinity of the recombinant cell types for ω -CgTx agrees well with that determined for intact IMR32 cells (36.5 ± 6.2 pM) (Table 1) but is different from measurements derived from crude homogenates of IMR32 cells (30).

There were significant differences in the receptor densities of the four recombinant cell types (Table 1). The B_{max} for ω -CgTx binding in $\alpha_{1B-1}\alpha_{2b}\beta_2$ -type cells was approximately ten times greater than that in $\alpha_{1B-1}\alpha_{2b}$ - and α_{1B-1} -type cells. The estimate for the binding capacity of the IMR32 cells correlates well with a previous report (30). The comparison of the B_{max} values suggests that the ω -CgTx-binding α_{1B-1} subunit is more efficiently expressed on the cell surface when co-expressed with the α_{2b} and β_2 subunits. Similarly, efficient expression of heteromeric protein complexes on the cell surface, such as nicotinic acetylcholine receptors, has been shown to require subunit assembly (31).

We performed whole cell recordings of HEK293 cells transfected with the cDNA encoding α_{1B-1} or with cDNAs encoding α_{1B-1} and α_{2b} or β_2 to assess functional contributions of the various subunits to the N-type channel activity. Currents recorded from $\alpha_{1B-1}\beta_2$ -transfected cells were observed at a frequency comparable to that of the $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells (16 of 46 cells; five independent transfections), consistent with a B_{max} of approximately 12,000 receptors per cell (Table 1). These currents resembled those observed in $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells, having similar current-voltage (I-V) curves, inactivation kinetics, and sensitivity to holding potential. Furthermore, $\alpha_{1B-1}\beta_2$ -mediated currents were irreversibly blocked by ω -CgTx (5 μ M; $n = 3$). However, currents in $\alpha_{1B-1}\beta_2$ -transfected cells were generally smaller in magnitude than those observed in $\alpha_{1B-1}\alpha_{2b}\beta_2$ cells and never exceeded 205 pA (15 pA/pF), with a mean of 91 pA (5.6 pA/pF). In contrast, currents in $\alpha_{1B-1}\alpha_{2b}\beta_2$ -transfected cells exceeded 200 pA in 57% of the cells tested (25).

Of 23 cells studied that were transfected with only α_{1B-1} (three independent transfections), two had small (20 to 40 pA) rapidly inactivating ($\tau = \sim 20$ ms) currents that were reversibly blocked by ω -CgTx. A similar current was detected in 1 of 11 $\alpha_{1B-1}\alpha_{2b}$ -transfected cells, whereas none of the untransfected HEK293 cells ($n = 17$) or HEK293 cells transiently expressing the α_{2b} and β_2 subunits ($n = 17$) displayed such currents. These results together with the relatively small B_{max} values observed in

α_{1B-1} -only and $\alpha_{1B-1}\alpha_{2b}$ -transfected cells (<2650 receptors per cell) further support the importance of the β subunit in the formation of functional N-type Ca^{2+} channels.

N-type Ca^{2+} channels characterized from different cell preparations have biophysically distinct properties that have made it difficult to distinguish N- and

L-type currents on the basis of inactivation properties. N-type Ca^{2+} channels were first described in chicken sensory neurons as high-voltage-activated Ca^{2+} channels that could be activated only from strongly negative holding potentials and inactivated within tens of milliseconds (27). Current remaining after decay of the inactivating component or currents activated from holding potentials ≥ -40 mV were believed to represent L-type channel activity. N-type Ca^{2+} channels have since been found to inactivate slowly and incompletely in some neuronal types (32). The range of inactivation rates observed in different tissues may be a result of a combination of factors, including distinct combinations of variant channel subunits and different states of regulation. Recent single channel analysis indicates that individual N-type channels can switch between transient and long-lasting modes of gating (33). Our whole cell data that show biphasic decay of a recombinantly expressed N-type Ca^{2+} channel are consistent with a population of channels that exhibit different gating modes.

Recent biochemical studies on brain ω -CgTx receptors have revealed proteins on SDS-polyacrylamide gel electrophoresis of a relative molecular mass consistent with α_1 , α_2 , and β subunits (29), although additional uncharacterized bands were also observed. Molecular biological evidence indicates that multiple α_1 , α_2 , and β transcripts, including α_{1B} , α_{2b} , and β_2 mRNAs, are co-expressed in IMR32 cells and hippocampal tissue (8), both sources of ω -CgTx binding sites (18, 30). The recombinant expression of α_{1B-1} , α_{2b} , and β_2 subunits to produce ω -CgTx-sensitive N-type channel activity confirms that an α_{1B} gene product mediates this activity. The functional necessity of a β subunit and modulation by an

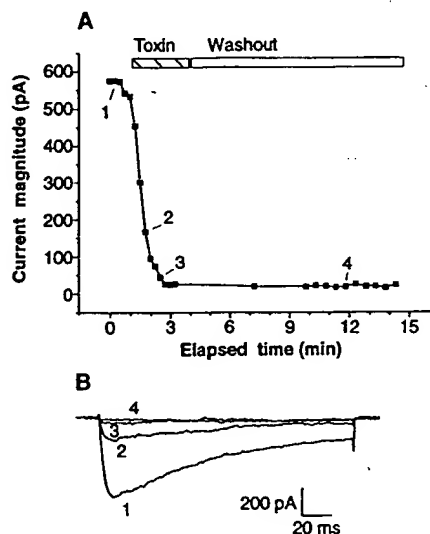

Fig. 4. Effect of ω -CgTx on I_{Ba} expressed in HEK293 cells transfected with α_{1B-1} , α_{2b} , and β_2 cDNAs (23). (A) Plot of peak current magnitude versus time before, during (hatched bar), and after (open bar) application of 5 μ M ω -CgTx. Test pulses (10 mV; holding potential = -90 mV) were delivered every 15 s before and during toxin application. Pulses were resumed every 30 s after recording of current-voltage relations from which only the current measured at 10 mV is shown. Similar results were obtained with the three concentrations of ω -CgTx tested: 0.5 μ M ($n = 3$), 5 μ M ($n = 7$), and 10 μ M ($n = 6$). (B) Example recordings made at points 1 to 4 of (A).

Fig. 5. Binding of ^{125}I - ω -CgTx. HEK293 cells were cotransfected with the α_{1B-1} , α_{2b} , and β_2 cDNAs (23) and assayed for specific binding of ^{125}I - ω -CgTx as a function of increasing concentration of ^{125}I - ω -CgTx (26); 2×10^5 cells were used in the assay mixture. (Inset) Scatchard analysis of the data. B, bound; F, free.

Table 1. Summary of Scatchard analysis of ω -CgTx binding to intact cells. HEK293 cells transfected with the indicated subunit cDNAs and IMR32 cells induced with dibutylryl cyclic AMP and bromodeoxyuridine (28) were assayed for saturation of specific ω -CgTx binding, and the data were analyzed by the Scatchard method (26). The B_{max} values determined from Scatchard analysis were corrected for transfection efficiency.

Cell line	K_d (pM)	B_{max} (sites/cell)
$\alpha_{1B-1}\alpha_{2b}\beta_2$	54.6 ± 14.5	$28,710 \pm 11,950$ ($n = 4$)
$\alpha_{1B-1}\beta_2$	38.8 ± 13.1	$11,860 \pm 5,910$ ($n = 4$)
$\alpha_{1B-1}\alpha_{2b}$	76.1 ± 15.5	$2,650 \pm 620$ ($n = 4$)
α_{1B-1}	59.1 ± 15.5	$2,085 \pm 880$ ($n = 4$)
IMR32	36.5 ± 6.2	$6,770 \pm 615$ ($n = 2$)

α_2 subunit are consistent with the recombinant functional expression of other α_1 subtypes (8, 11), although expression of α_{1B-1} alone appears sufficient for ω -CgTx binding.

Our results suggest that multiple subtypes of the N-type channel might exist as a result of the heterogeneity of the subunits that comprise the channel complex. Co-expression of three different β gene products with the rabbit cardiac (α_{1C}) subunit alters the channel properties and thus indicates that subunit composition can determine distinct, voltage-dependent Ca^{2+} channels (6). At least two forms each of α_{1B} , α_2 , and β transcripts expressed in the brain are products of differential processing (6, 8, 34). This heterogeneity of the α_{1B} , α_2 , and β subunits is consistent with biophysically distinct N-type channels characterized from different cell preparations. Recombinant expression of each of the α_{1B} , α_2 , and β forms might reveal multiple N-type channels and the functional consequence of various subunit combinations (35).

- Recombinant cDNA libraries were prepared, and overlapping α_{1B-1} cDNA clones were isolated from IMR32, human hippocampus, and basal ganglia cDNA libraries and characterized essentially as described (3, 8).
- We performed PCR analyses as described (8) using IMR32 RNA, human hippocampus RNA, and human genomic DNA with α_{1B-1} -specific primers [nucleotides (nt) 6368 to 6391 and the complement of nt 7071 to 7095] to confirm the α_{1B} termination codon. The RNAs gave the expected 728-bp fragment (α_{1B-1}) as well as a 541-bp fragment (α_{1B-2}). The genomic DNA product was ~1350 bp. The DNA sequences of α_{1B-1} and α_{1B-2} diverge from each other after nt 6489. The α_{1B-1} subunit contains an additional 187-bp exon that alters the reading frame. After this exon, the α_{1B-1} and α_{1B-2} sequences are identical for the remaining 419 nucleotides characterized from both sequences, α_{1B-1} nt 6677 to 7095 and α_{1B-2} nt 6490 to 6908. The presence of the exon (α_{1B-1}) results in the termination of the coding sequence at nt 7018 to 7020 (TAG); the absence of the exon (α_{1B-2}) results in the termination of the coding sequence at nt 6712 to 6714 (TGA). Differential processing of the α_{1B} primary transcript was confirmed by characterization of the α_{1B} genomic PCR product. An ~270-bp intron was identified between α_{1B-1} nt 6489 and 6490. The α_{1B-1} and α_{1B-2} transcripts result from alternative selection of splice acceptor sites. α_{1B-1} is formed by selection of the splice acceptor at the intron-exon boundary, at nt 6490 on the exon side of the boundary; α_{1B-2} is formed by selection of a splice acceptor identified by an AG dinucleotide at nt 6675 and 6676 of the α_{1B-1} coding sequence.
- Tissue distribution of the α_{1B-1} and α_{1B-2} transcripts was determined by PCR assays with oligonucleotide primers, nt 6447 to 6470 (Pro²¹⁴⁹ to Glu²¹⁵⁷), and the complement of α_{1B-1} -specific nt 6819 to 6843 (Leu²²⁷³ to Glu²²⁸¹). PCR products were probed with an α_{1B-1} -specific oligonucleotide (nt 6513 to 6536; Ser²¹⁷¹ to Ala²¹⁷⁹) and an α_{1B-2} -specific oligonucleotide (nt 6480 to 6498; Pro²¹⁶⁰ to Ser²¹⁶⁶). The expected size bands were 396 bp (α_{1B-1}) and 209 bp (α_{1B-2}).
- pcDNA α_{1B-1} was constructed in pcDNA1 (Invitrogen, San Diego, CA) with $\alpha_{1.179}$ (nt -143 to 2194), $\alpha_{1.177}$ (nt 2194 to 4160), $\alpha_{1.201}$ (nt 4160 to 5305), $\alpha_{1.200}$ (nt 5305 to 6116), and $\alpha_{1.230}$ (nt 6116 to 7176). DNA sequence analysis revealed that $\alpha_{1.177}$ has a two-nucleotide deletion (nt 3711 to 3712; Ser¹²³⁷) that was corrected with a PCR-amplified IMR32 Nar I-Kpn I fragment (nt 3685 to 4160; Gly¹²²⁹ to Gly¹³⁸⁷). pHBcCa α_{2B} (A) and pHBcCa α_{2B} -RBS(A), full-length α_{2B} and β_2 constructs in pcDNA1, were described previously (8). HEK293 cells [B. W. Stillman and Y. Gluzman, *Mol. Cell. Biol.* 5, 2051 (1985)] were grown as a monolayer culture in Dulbecco's modified Eagle's medium (Gibco) containing 5% defined-supplemented bovine calf serum (Hyclone) plus penicillin G (100 U/ml) and streptomycin sulfate (100 μ g/ml). HEK293 cell transfections were mediated by calcium phosphate [F. M. Ausubel *et al.*, Eds., *Current Protocols in Molecular Biology* (Wiley, New York, 1990), pp. 9.1.1 to 9.1.7]. Cells were transfected (2×10^6 per polylysine-coated plate). Standard transfections (10-cm dish) contained 8 μ g of pcDNA α_{1B-1} , 5 μ g of pHBcCa α_{2B} (A), 2 μ g of pHBcCa α_{2B} -RBS(A), 2 μ g of pCMV β (Clontech β -galactosidase expression plasmid), and pUC18 to maintain a constant mass of 20 μ g/ml. Cells were analyzed 48 to 72 hours after transfection. Transfection efficiencies ($\pm 10\%$) were determined by *in situ* histochemical staining for β -galactosidase activity [J. R. Sanes, J. L. R. Rubenstein, J.-F. Nicolas, *EMBO J.* 5, 3133 (1986)]. Transfection efficiencies generally were >50%.
- Properties of recombinantly expressed Ca^{2+} channels were studied by whole cell patch-clamp techniques [O. P. Hamill, A. Marty, E. Neher, B. Sakmann, F. J. Sigworth, *Pfluegers Arch.* 391, 85 (1981)]. Recordings were performed on transfected HEK293 cells 2 to 3 days after transfection. Cells were plated at 100,000 to 300,000 cells per polylysine-coated, 35-mm tissue culture dishes (Falcon, Oxnard, CA) 24 hours before recordings. Cells were perfused with 15 mM BaCl₂, 125 mM choline chloride, 1 mM MgCl₂, and 10 mM Hepes (pH = 7.3) adjusted with tetraethylammonium hydroxide (bath solution). Pipettes were filled with 135 mM CsCl, 10 mM EGTA, 10 mM Hepes, 4 mM Mg-adenosine triphosphate (pH = 7.5) adjusted with tetraethylammonium hydroxide. Sylgard (Dow-Corning, Midland, MI)-coated, fire-polished, and filled pipettes had resistances of 1 to 2 megohm before we established gigohm seals to cells. ω -CgTx (Bachem, Bay K 8644, and nifedipine (Research Biochemicals, Natick, MA) were prepared as described (8), dissolved in bath solution, and continuously applied by means of puffer pipettes as required for a given experiment. Recordings were performed at room temperature (22° to 25°C). Series resistance compensation (70 to 85%) was employed to minimize voltage error that resulted from pipette access resistance, typically 2 to 3.5 megohm. Current signals were filtered (-3 dB, 4-pole Bessel) at a frequency of 1/4 to 1/5 the sampling rate, which ranged from 0.5 to 3 kHz. Voltage commands were generated, and data were acquired with CLAMPX (pClamp, Axon Instruments, Foster City, CA). All data shown are corrected for linear leak and capacitive components as described (8). Exponential fitting of currents was performed with CLAMPFIT (Axon).
- Currents <30 pA were not included because of unreliable measurements. For $\alpha_{1B-1}\alpha_{2B}\beta_2$ -transfected cells, currents in 43.6% of the expressing cells ranged from 30 to 200 pA, 43.6% of the cells had currents that ranged from 200 to 1000 pA, and 12.8% had currents that exceeded 1000 pA.
- We mechanically removed cells from tissue culture plates 48 hours after transfection by spraying with phosphate-buffered saline that contained 0.1% (w/v) bovine serum albumin (BSA). The cells were collected, washed once, and resuspended in assay buffer [10 mM Hepes (pH 7.4), 140 mM NaCl, 5 mM KCl, 12 mM glucose, and BSA (1 mg/ml)]. Specific binding of [¹²⁵I]- ω -CgTx to transfected cells was determined as described (30) with several modifications. Briefly, we performed the assay in 12 mm \times 75 mm polypropylene tubes in 0.5 ml of assay buffer by incubating the cells with 100 pM [¹²⁵I]- ω -CgTx (DuPont Biotechnology Systems; 2200 Ci/mmol) for 1 hour at 37°C. Subsequently, 2 ml of ice-cold wash buffer [5 mM Hepes (pH 7.4), 160 mM choline chloride, 1.5 mM CaCl₂, and BSA (1 mg/ml)] was added to each tube, and the mixtures were centrifuged at 2300g for 30 min at 4°C. The pellets were washed again and counted for radioactivity. Nonspecific binding was determined in the presence of 20 nM unlabeled ω -CgTx. The optimum cell number was determined by a titration of 1×10^5 to 2×10^6 cells per assay tube. For saturation binding studies, the binding of [¹²⁵I]- ω -CgTx was measured as a function of increasing concentration of [¹²⁵I]- ω -CgTx. Nonspecific binding was subtracted at each concentration. Specific binding was plotted as a function of [¹²⁵I]- ω -CgTx concentration and analyzed by the Scatchard method.

Membrane Depolarization Induces p140^{Trk} and NGF Responsiveness, But Not p75^{LN^{GR}}, in MAH Cells

Susan J. Birren, Joseph M. Verdi, David J. Anderson*

Nerve growth factor (NGF) is required for the maturation and survival of sympathetic neurons, but the mechanisms controlling expression of the NGF receptor in developing neuroblasts have not been defined. MAH cells, an immortalized sympathoadrenal progenitor cell line, did not respond to NGF and expressed neither low-affinity NGF receptor (p75) nor p140^{Trk} messenger RNAs. Depolarizing concentrations of potassium chloride, but none of a variety of growth factors, induced expression of p140^{Trk} but not p75 messenger RNA. A functional response to NGF was acquired by MAH cells under these conditions, suggesting that expression of p75 is not essential for this response. Depolarization also permitted a relatively high proportion of MAH cells to develop and survive as neurons in fibroblast growth factor and NGF. These data establish a relation between electrical activity and neurotrophic factor responsiveness in developing neurons, which may operate in the functioning of the mature nervous system as well.

The survival of vertebrate neurons is dependent on neurotrophic factors secreted by their postsynaptic targets. NGF, the prototypic neurotrophic factor, is required for the survival of sympathetic and some sensory neurons (1). The embryonic precursors to sympathetic neurons neither respond to nor require NGF (2–4). This raises the question of how developing sympathetic neuroblasts acquire their responsiveness to and dependence on NGF. We have studied this process with the use of MAH cells a retrovirally immortalized sympathoadrenal progenitor cell line (5). The identification of the product of the proto-oncogene *trk*, p140^{Trk} (Trk), as a signal-transducing subunit of the NGF receptor (NGFR) (6, 7) has allowed us to use Trk mRNA expression to assay environmental signals that may induce NGF responsiveness in MAH cells. Here we identify membrane depolarization as one such signal.

MAH cells, like the nonimmortalized progenitors from which they derive, do not undergo neuronal differentiation in response to NGF. The protein p75, the low-affinity NGFR (8, 9), is not expressed by these cells (5). MAH cells grown in the absence of added factors also express little or no Trk mRNA (Fig. 1A, lanes 1 and 2). Thus, the failure of these precursor cells to respond to NGF correlates with their lack

of expression of both types of NGFR mRNAs. We then sought to identify factors that induce expression of NGFR and NGF responsiveness. Previously, we found that basic fibroblast growth factor (bFGF) induced low levels of p75 expression and NGF responsiveness in a small subpopulation of MAH cells (5). However, bFGF failed to induce significant Trk expression in MAH cells, as did a number of other growth and neurotrophic factors (Fig. 1A, lanes 4 through 7, and data not shown). In addition, retinoic acid, which induces high-affinity NGF receptors and NGF dependence in chick sympathetic neuroblasts (10), did not induce Trk mRNA (Fig. 1A, lane 8).

In the chick, depolarization increases the survival of NGF-dependent sympathetic neurons (4). In MAH cells, depolarization stimulated the survival of postmitotic neurons. Depolarization of MAH cells produced by the addition of 40 mM KCl led to an induction of Trk mRNA (Fig. 1A, lane 3). A time course in 40 mM KCl revealed that Trk expression was detectable within 24 hours and reached maximal amounts within 3 days (Fig. 1C, lanes 5 through 8). Reprobing of the same blots with p75 probes revealed that, in contrast to Trk mRNA, p75 mRNA was not induced by 40 mM KCl.

MAH cells require dexamethasone (dex) for long-term survival; when dex is removed, the cells die within 4 to 5 days. In the presence of 5 μ M dex, a low steady-state amount of Trk mRNA was detected (Fig. 1B, lane 2). However, even in the

presence of dex an up-regulation of Trk mRNA by 40 mM KCl occurred (Fig. 1B, lane 3), indicating that the effect of depolarization is not simply to maintain the survival of Trk-expressing MAH cells. The time course of Trk induction by 40 mM KCl was similar in the presence of dex (Fig. 1D, lanes 6 through 9) as in its absence, although higher steady-state amounts of Trk mRNA were produced in the presence of dex (compare Fig. 1D, lane 8, with Fig. 1C, lane 7). As was the case in the absence of dex, no induction of p75 mRNA was detected in 40 mM KCl plus dex.

The effect of 40 mM KCl is likely to be produced by membrane depolarization because no induction of Trk mRNA was observed in 40 mM NaCl (Fig. 1, A and B, lanes 9). Moreover, veratridine, an Na⁺ channel agonist that leads to membrane depolarization, also caused an increase in the amount of Trk mRNA concentrations (data not shown). In PC12 cells, the induction of immediate-early gene expression by membrane depolarization requires the opening of voltage-gated Ca²⁺ channels and depends on extracellular Ca²⁺ (11). Removal of extracellular Ca²⁺ or addition of dihydropyridine antagonists of voltage-gated Ca²⁺ channels resulted in the death of MAH cells within 24 hours, precluding our ability to determine a requirement for Ca²⁺ influx in Trk induction. However, at suboptimal concentrations of KCl (20 mM) (Fig. 1E, lane 4), the Ca²⁺ channel agonist Bay K 8644 potentiated the induction of Trk mRNA (Fig. 1F, lanes 3 and 4), which suggests that Ca²⁺ influx through voltage-gated L-type Ca²⁺ channels is indeed involved in the induction of Trk mRNA by membrane depolarization.

We then sought to determine whether depolarization induces a functional response to NGF. We used two assays of NGF responsiveness: neurite outgrowth and cell number. Cell number reflects both the survival and proliferation-promoting (12) effects of NGF, although for technical reasons it is difficult to determine the relative contributions of these two processes in this system. NGF responses were assayed after 5 days, by which time most MAH cells had died in control medium (Table 1). Those few cells that survived showed little process outgrowth (Fig. 2A). Similar results were obtained in NGF alone (Fig. 2B and Table 1), indicating that MAH cells do not respond to this factor. Cell number was significantly increased by depolarizing concentrations of KCl (Table 1), although little neurite outgrowth was observed (Fig. 2C). In NGF plus 40 mM KCl, cell number was even higher (Table 1) and the cells bore long neurites (Fig. 2D). These neurite-bearing cells, however, lacked the cell soma hypertrophy characteristic of mature neu-

Summary

The primary structures of human neuronal α_1 , α_2 , and β subunits of a voltage-dependent Ca^{2+} channel were deduced by characterizing cDNAs. The α_1 subunit (α_{1D}) directs the recombinant expression of a dihydropyridine-sensitive L-type Ca^{2+} channel when coexpressed with the β (β_2) and the α_2 (α_{2b}) subunits in *Xenopus* oocytes. The recombinant channel is also reversibly blocked by 10–15 μM ω -conotoxin. Expression of the α_{1D} subunit alone, or coexpression with the α_{2b} subunit, did not elicit functional Ca^{2+} channel activity. Thus, the β_2 subunit appears to serve an obligatory function, whereas the α_{2b} subunit appears to play an accessory role that potentiates expression of the channel. The primary transcripts encoding the α_{1D} , α_2 , and β subunits are differentially processed. At least two forms of neuronal α_{1D} were identified. Different forms of α_2 and β transcripts were also identified in CNS, skeletal muscle, and aorta tissues.

Introduction

The primary pathway by which Ca^{2+} enters excitable cells is through voltage-dependent Ca^{2+} channels present in cellular membranes (Bean, 1989). Multiple subtypes of these channels have been identified (Hess, 1990), the best characterized of which is the rabbit skeletal muscle dihydropyridine (DHP)-sensitive Ca^{2+} channel, consisting of four tightly coupled subunits, α_1 , α_2 , β , and γ (Campbell et al., 1988). Each of these subunits has been characterized by cDNA cloning (Tanabe et al., 1987; Ellis et al., 1988; Ruth et al., 1989; Jay et al., 1990). Recent evidence suggests that different α_1 subunits are encoded by a gene family comprising at least five distinct genes, some of which are expressed in several tissues (Ellis et al., 1988; Mikami et al., 1989; Perez-Reyes et al., 1990; Snutch et al., 1990). The gene encoding the α_1 subunit expressed in rabbit skeletal muscle directs the recombinant expression of a functional DHP-sensitive Ca^{2+} channel in cultured myotubes of *mdg* mice and in mouse L cells (Tanabe et al., 1988; Perez-Reyes et al., 1989). A second gene, encoding α_1 subunits expressed in rabbit cardiac and lung tissues, directs the synthesis of

DHP-sensitive Ca^{2+} channels in *Xenopus* oocytes (Mikami et al., 1989; Biel et al., 1990). In contrast, a third α_1 subunit gene, expressed in rabbit brain, directs the synthesis of Ca^{2+} channels that are insensitive to both DHPs and ω -conotoxin GVIA (ω -CgTx) when coexpressed with the rabbit skeletal muscle α_2 and β subunits in *Xenopus* oocytes (Mori et al., 1991). These expression studies in oocytes demonstrated that the α_1 subunit forms the pore through which Ca^{2+} enters the cell. The functional expression of α_1 subunits encoded by the two remaining genes has not yet been reported.

The entry of Ca^{2+} through voltage-dependent Ca^{2+} channels in neurons controls diverse functions, such as neurotransmitter release, excitability, and differentiation (Tsien et al., 1988). On the basis of biophysical and pharmacological characterizations, four subtypes of neuronal voltage-dependent Ca^{2+} channels have been proposed (Llinás et al., 1989; Swandulla et al., 1991). Although specific neuronal functions have been ascribed to different Ca^{2+} channel subtypes, the analysis has been difficult due to the coexistence of multiple subtypes in individual cells (Miller, 1987; Bean, 1989; Hess, 1990; Swandulla et al., 1991). One important step in defining subtype-function relationships is the cloning and expression of each neuronal subtype as a pure population. We report the complete amino acid sequence and functional expression of three subunits of a human neuronal L-type voltage-dependent Ca^{2+} channel: an α_1 subunit (designated α_{1D}), an α_2 subunit (designated α_{2b}), and a β subunit (designated β_2). A description of the nomenclature used to designate the different Ca^{2+} channel subunits is provided in the Experimental Procedures. We also report tissue-specific processing of the α_2 and β transcripts.

Results

Cloning and Characterization of Three Human Neuronal Voltage-Dependent Ca^{2+} Channel Subunits

We previously reported the isolation of cDNAs that encode the α_1 , α_2 , β , and γ subunits of the rabbit skeletal muscle DHP-sensitive, L-type Ca^{2+} channel (Ellis et al., 1988; Jay et al., 1990). These subunit cDNAs were used as probes to isolate related human neuronal cDNAs as described in the Experimental Procedures. The primary structures of the human neuronal α_{1D} , α_{2b} , and β_2 subunits (Figure 1; see Figure 3 and Figure 4) were deduced from these cDNA sequences.

α_{1D} Subunit

The primary structure of the human α_{1D} subunit (Figure 1) comprises 2161 amino acids, yielding a calculated molecular weight of 245,163. The α_{1D} sequence is most similar (96.3% deduced amino acid sequence identity) to the previously reported 188 amino acid

—

partial rat brain class D cDNA (Snutch et al., 1990). The translation initiation site was assigned to the first methionine codon that appears downstream of an in-frame nonsense codon. Interestingly, 7 methionine codons appear at the beginning of the putative coding sequence, followed by 2 lysine codons and an eighth methionine codon; none of these methionine codons are contained within the consensus sequence for eucaryotic initiation codons (Kozak, 1987). This series of methionine codons was confirmed by direct sequence analysis of cloned polymerase chain reaction (PCR) products derived from reactions performed on human neuroblastoma IMR32 cell cytoplasmic RNA, as described in the Experimental Procedures.

The predicted structure of the α_{10} subunit consists of four repeating domains, each domain comprised of five hydrophobic segments (S1, S2, S3, S5, and S6) and one positively charged segment (S4), suggesting the same transmembrane topology as described previously for Ca^{2+} channel α_1 subunits and Na^+ channels (Noma and Noda, 1986; Tanabe et al., 1987; Mikami et al., 1989; Biel et al., 1990; Koch et al., 1990; Mori et al., 1991). Based on this proposed topology, the α_{10} subunit has 3 of 12 potential N-glycosylation sites (Bause, 1983) assigned to the extracellular side and nine of ten potential cAMP-dependent phosphorylation sites (Glass et al., 1986) and 22 of 26 potential protein kinase C phosphorylation sites (Woodgett et al., 1986) assigned to the cytoplasmic side of the cellular membrane (Figure 2).

The α_{10} cDNA clone $\alpha_{1.136}$ was found to encode an incompletely processed transcript containing two exons encoding the IS6 transmembrane domain, designated α_{10} exon A and α_{10} exon B. The deduced amino acid sequences are MNDAMGFELPWVYFVSLVIFCSFFVLNLVLGVLGS and VNDALGWEWPWVYFVSLIILGSFFVLNLVLGVLGS, respectively, which share 83% identity. Exon A was present in clone $\alpha_{1.144}$, which was used for the construction of the full-length α_{10} cDNA used in the present study (Figure 1).

The deduced amino acid sequences of two different α_1 subunits, the rabbit cardiac (Mikami et al., 1989) and the rabbit brain BI-2 (Mori et al. 1991), previously expressed in *Xenopus* oocytes, are shown aligned with the human α_{10} sequence (Figure 2). The amino acid sequence identity of α_{10} to these sequences is significant: 70.3% and 40.5% for the cardiac and BI-2 sequences, respectively. The sequence identity is well conserved through the four repeating domains, 79.7% and 50.5% for the α_{10} -cardiac and the α_{10} -BI-2 pairs, respectively. Most noteworthy is the divergence of the α_{10} and cardiac sequences compared with the BI-2 sequence through the putative DHP-binding region (Regulla et al., 1991). In this region, the α_{10} and cardiac DHP-sensitive forms differ by a single amino acid (Ser-1490) as does the rabbit skeletal muscle sequence (Ala-1404), whereas the BI-2 DHP-insensitive form has 18 amino acid substitutions in this region (Figure 2). This evidence, together with the results of the expression studies reported here (see below), supports the proposed identity of the DHP-binding region.

α_{2b} Subunit

The primary structure of the human brain α_{2b} subunit (Figure 3) consists of 1091 amino acids, yielding a calculated molecular weight of 123,182. The amino acid sequence homology is 97.1% identical to the rabbit skeletal muscle α_{2a} subunit sequence (Figure 3) and has essentially an identical predicted topography and secondary structure (Ellis et al., 1988; Jay et al., 1991), with the exceptions of a 19 amino acid deletion in the human sequence compared with the rabbit sequence (α_{2a} residues Pro-507 to Gln-525) and a 7 amino acid insertion in the human sequence compared with the rabbit sequence (α_{2b} residues Lys-602 to Asp-608). The 16 potential glycosylation sites that were identified in the rabbit skeletal muscle α_{2a} subunit (Jay et al., 1991) also are conserved in the human α_{2b} sequence. Previous studies suggest that posttranslational processing of the rabbit skeletal α_{2a} subunit results in a heterogeneous population of 8 peptides, all of which begin at Ala-935 (Jay et al., 1991). The human brain α_{2b} sequence has two conservative amino acid substitutions at this proposed cleavage site, Val-923 and Glu-924 replacing Ala-935 and Asp-936, respectively (Figure 3).

β_1 and β_3 Subunits

The primary structure of the human brain β_2 subunit (Figure 4) comprises 478 amino acids and has a calculated molecular weight of 52,934. The amino acid sequence homology is 96.9% identical to the rabbit skeletal muscle β_1 subunit sequence (Figure 4). The β_2 subunit has essentially an identical topography and secondary structure as predicted for the rabbit skeletal muscle β_1 subunit (Ruth et al., 1989) except that the deduced human β_2 sequence has a deletion of 45 amino acids (Ala-217 to Lys-261). The lack of this region in β_2 removes the second α helical domain proposed for the rabbit skeletal muscle β_1 subunit (Ruth et al., 1989). Thirteen of sixteen potential phosphorylation sites identified in the rabbit skeletal muscle β_1 subunit (Ruth et al., 1989) are conserved in the human β_2 sequence (Figure 4). Two sites are changed due to amino acid substitutions (β_1 Ser-179 and Ser-182), and the third is removed by the 45 amino acid deletion (β_1 Ser-238).

Another form of β , designated β_3 , which has the same deduced 45 amino acid deletion, was identified in the hippocampus cDNA library. Clone $\lambda\beta_4$ encodes the β_3 cDNA and diverges from β_2 after nucleotide 1332. The β_3 cDNA extends another 429 nucleotides with no translation stop codon identified (data not shown). A GT splice donor is not present at the point of divergence between the β_2 and β_3 sequences. A complete characterization of β_3 is in progress.

Tissue-Specific Processing of the α_1 and β Transcripts and Distribution of α_{10} , α_{2a} , and β mRNAs

PCR analysis and hybridization with oligonucleotides derived from α_{2a} - or α_{2b} -specific regions (the 19 amino acid region or the 7 amino acid region, respectively; Figure 3) demonstrated that the human skeletal

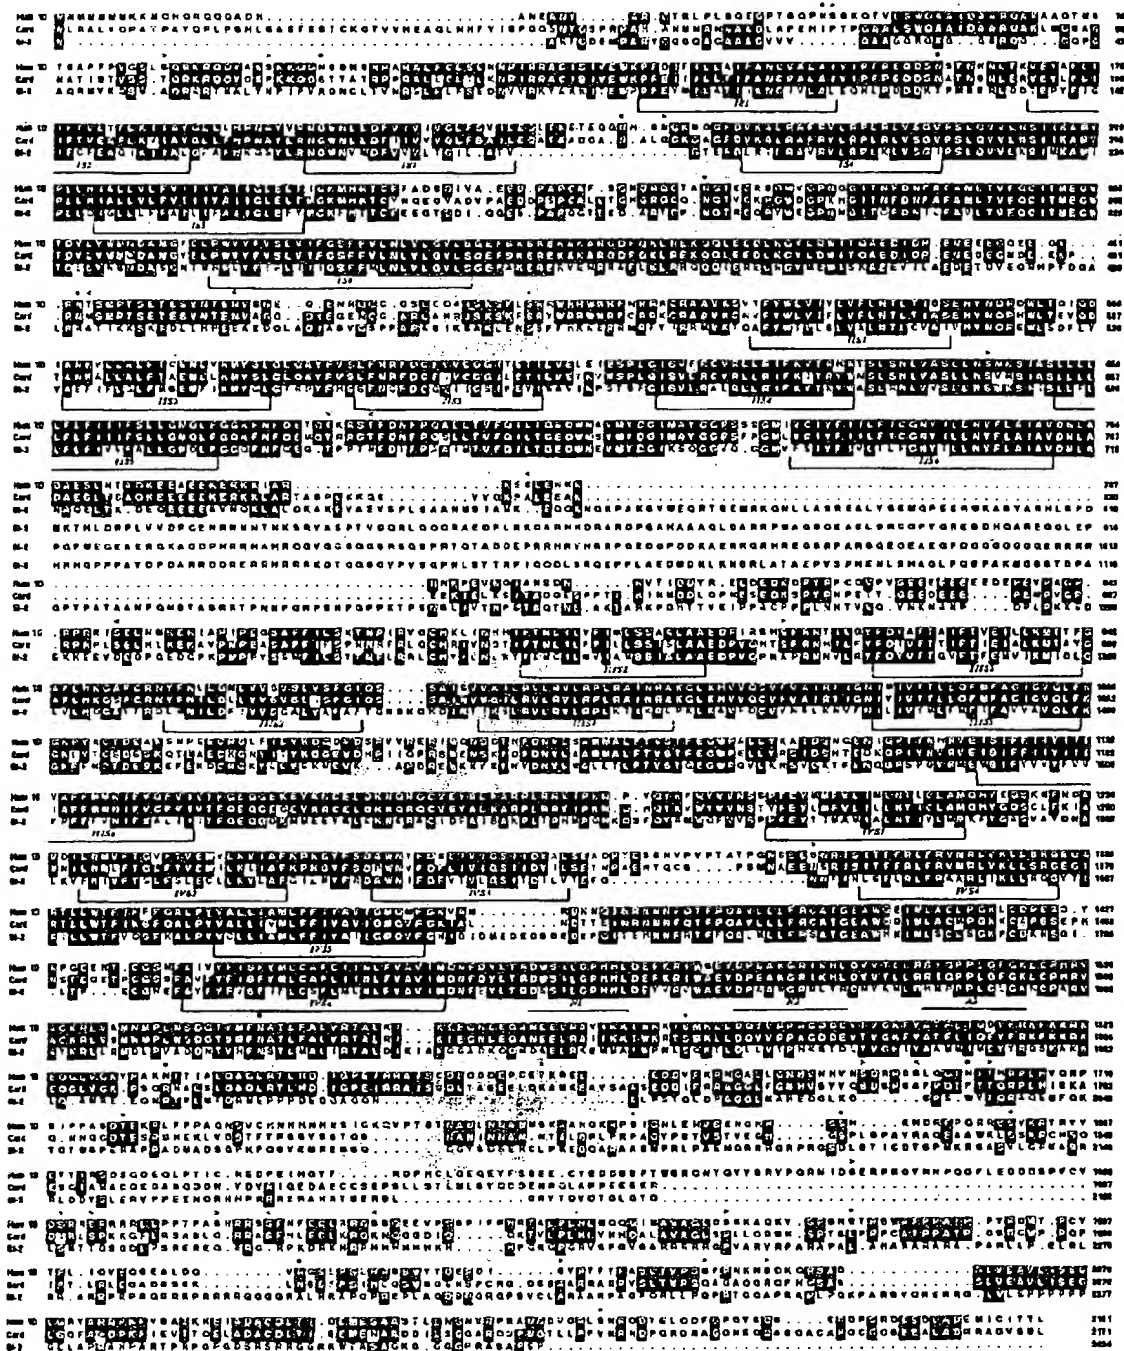

Figure 2. Alignment of Deduced Amino Acid Sequences of α_1 Subunits

The amino acid sequences of the human neuronal Ca^{2+} channel α_{1D} (Hum 1D), the rabbit cardiac α_1 (Card; Mikami et al., 1989), and the rabbit brain α_1 (BI-2; Mori et al., 1991) are shown in single-letter code. The numbering begins with the proposed initiating methionine. The number of the amino acid residue at the end of each line is given. Identical residues at one position in two of the three sequences are shown as white letters on black background. The putative transmembrane segments S1-S6 in each of the repeats I-IV are shown (brackets). The putative DHP-binding regions (N1, N2, A2; R  gulla et al., 1991) are shown (underlined). Potential N-glycosylation (o), cAMP-dependent phosphorylation (K), and protein kinase C phosphorylation (D) sites are shown. Potential targets of either kinase are labeled (+).

Figure 3. Determined cDNA Sequence of α_{2b} and Alignment of the Deduced Amino Acid Sequence with the Deduced Rabbit Skeletal Muscle α_{2b} Sequence

For the rabbit α_2 sequence (Rab; Ellis et al., 1988), only the amino acid differences compared with the human α_2 sequence (Hum) are shown. The 5' untranslated sequence is negatively numbered. Positive numbering begins at the first nucleotide of the proposed initiating codon. The number of the nucleotide and amino acid residue is given at the end of each line. Negative numbers for amino acids designate residues contained in the proposed signal sequence (Ellis et al., 1988) beginning with the initiating methionine (-24 and -29). The positive numbering begins at the NH_2 -terminal residue (glutamic acid) of the mature protein. Amino acid sequence differences and insertions/deletions are identified by the black boxes. Potential N-glycosylation (u), cAMP-dependent phosphorylation (C), and protein kinase C phosphorylation (X) sites are shown. The potential target of either kinase is labeled (+).

muscle α_2 transcript is processed in a manner similar to the rabbit skeletal muscle transcript (540 bp bands; Figure 5A). Furthermore, the α_2 transcripts expressed in IMR32 cells and human CNS tissues (501 bp bands; Figure 5B) and the α_2 transcript expressed in aorta tissue (490 bp band; Figure 5B) are processed differentially to yield at least two additional α_2 transcript species, α_{2b} (Figure 3) and α_{2c} , respectively.

PCR analysis of β -specific RNAs showed that the β primary transcript is also processed in a tissue-specific manner. Analysis of human skeletal muscle RNA detected the 135 nucleotides absent in β_2 (Figure 4) and, thus, confirmed the presence of a distinct skeletal muscle β_1 transcript (Figure 5C). In addition to the β_1 form expressed in skeletal muscle and the β_2 and β_3 forms expressed in the CNS, another form, designated β_4 , was detected in aorta tissue having a 156 nucleotide deletion relative to the skeletal muscle β_1 transcript (Figure 5C).

To confirm the tissue-specific processing of the β subunit primary transcript, β -specific PCR products of human skeletal muscle and aorta were cloned, and the DNA sequence was determined. The deduced human skeletal muscle amino acid sequence is 92% identical to the rabbit skeletal muscle sequence from position Gly-210 to Lys-261 (Figure 4). The β_2 sequence has a proposed alternative exon (Ala-210 to Ser-216) that

probably corresponds to either the human skeletal muscle sequence Gly-210 to Leu-216 (GNEMTNL) or Arg-255 to Lys-261 (RIPFFKK). The deduced aorta sequence lacks the region between residues Ser-209 and Thr-217 (Figure 4).

PCR analysis performed on RNAs isolated from several human primary tissues and IMR32 cells identified an α_{10} transcript in IMR32 cells and each of the human CNS tissues, but not in human skeletal muscle (Figure 5D). An α_2 transcript was detected in all RNAs analyzed (Figures 5A and 5B), as was a β transcript (Figure 5C).

Functional Expression in *Xenopus* Oocytes

The expression of the human neuronal α_{10} , α_{2b} , and β_2 subunits was studied in *Xenopus* oocytes. mRNAs encoding each subunit were synthesized *in vitro* and were injected into oocytes either alone or in various combinations. The oocytes then were examined for inward Ba^{2+} currents (I_{Ba}) mediated by voltage-dependent Ca^{2+} channels.

Oocytes coinjected with the α_{10} , α_{2b} , and β_2 mRNAs expressed sustained I_{Ba} upon depolarization (162 ± 121 nA, $n = 46$) that typically showed little inactivation during test pulses ranging from 140–700 ms (Figure 6A). A series of voltage steps revealed currents that appeared at approximately -30 mV and peaked at approximately 0 mV (Figure 6B). Application of the DHP

Figure 4. Determined cDNA Sequence of β_2 and Alignment of the Deduced Amino Acid Sequence with the Deduced Rabbit Skeletal Muscle β_1 Sequence

For the rabbit β_1 sequence (Rab; Ruth et al., 1989), only the amino acid differences compared with the human β_2 sequence (Hum) are shown. See legend of Figure 3 for description of symbols and numbering.

Ca^{2+} channel agonist Bay K 8644 increased the magnitude of the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated currents, prolonged the "tail" currents present upon repolarization of the cell, and induced a hyperpolarizing shift in current activation (Figures 6A and 6B). Application of the DHP Ca^{2+} channel antagonist nifedipine blocked a substantial fraction of the I_{Ca} in oocytes coinjected with α_{10} , α_{2b} , and β_2 (91% \pm 6%, $n = 7$; Figure 6C). Much of the I_{Ca} recovered when the holding potential was shifted from -50 mV to -90 mV (data not shown), consistent with the voltage-dependent block by nifedipine (Bean, 1984; Sanguinetti and Kass, 1984). A residual inactivating component of I_{Ca} typically remained after nifedipine application. Consistent with previous studies on neuronal L-type Ca^{2+} channels (Fox et al., 1987), the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated I_{Ca} was blocked completely by $50 \mu\text{M}$ Cd^{2+} , but only approximately 15% by $100 \mu\text{M}$ Ni^{2+} .

The $\alpha_{10}\alpha_{2b}\beta_2$ -mediated I_{Ca} was blocked weakly (54% \pm 29%, $n = 7$) and reversibly by relatively high concentrations (10–15 μM) of $\omega\text{-CgTx}$ (Figure 6D). Bay K 8644 was first applied to the cell in order to determine the effect of $\omega\text{-CgTx}$ on the DHP-sensitive current component that was distinguished by the prolonged tail currents. Both the test currents and the accompanying tail currents were blocked progressively within 1–3 min after application of $\omega\text{-CgTx}$, but both recovered partially as the $\omega\text{-CgTx}$ was flushed from the bath.

The contribution of the α_{2b} and β_2 subunits to the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated current was assayed by expression of the α_{10} subunit alone or in combination with either the β_2 subunit or the α_{2b} subunit. Oocytes injected with only the α_{10} mRNA produced no discernable I_{Ca} upon depolarization ($n = 10$). Oocytes coinjected with the α_{10} and β_2 mRNAs expressed I_{Ca} (108 \pm 39 nA, $n = 4$) that resembled the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated currents,

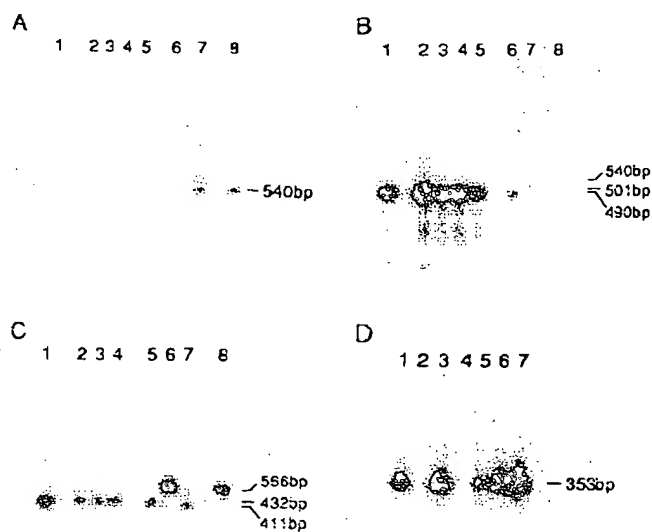

Figure 5. Autoradiographs of PCR Products Showing Distribution of Voltage-Dependent Ca^{2+} Channel Subunit Transcripts and Alternative Splicing of the α_2 and β Transcripts

IMR32 cytoplasmic RNA and human primary tissue poly(A)⁺ RNAs were used as templates to synthesize cDNA prior to PCR analysis.

(A and B) PCR products of pHB $\text{CaCH}\alpha_2$, a human brain α_2 cDNA clone (lane 1), IMR32 cells (lane 2), hippocampus and basal ganglia (lane 3), habenula (lane 4), thalamus (lane 5), aorta (lane 6), skeletal muscle (lane 7), and p α_2 .15 Δ S, a rabbit skeletal muscle α_2 clone (lane 8), were hybridized with (A) an α_2 oligonucleotide (nucleotides 1597–1619 corresponding to Pro-507 to Thr-514; Ellis et al., 1988) or (B) an α_2 oligonucleotide (nucleotides 1876–1896 corresponding to Lys-602 to Asp-608). The PCR reactions were primed with human α_2 oligonucleotides, nucleotides 1455–1479, and the complement of nucleotides 1931–1955. An approximately equal mass of DNA was present in each lane. The sizes of the 490 bp, 501 bp, and 540 bp α_2 -specific PCR products derived from human aorta, IMR32 cell and CNS tissues, and skeletal muscle RNAs, respectively, were further

confirmed by electrophoresis through a 1% agarose/2% NuSieve composite gel. The weaker hybridization of the human α_2 -derived oligonucleotide with the 490 bp aorta and 540 bp skeletal muscle PCR products further supports their difference from the α_2 transcript. Each band observed also hybridized with an α_2 tissue nonspecific probe, nucleotides 1601–1626 (data not shown).

(C) PCR products of pHB $\text{CaCH}\beta_1$, a human brain β_1 cDNA clone (lane 1), IMR32 cells (lane 2), hippocampus and basal ganglia (lane 3), habenula (lane 4), thalamus (lane 5), skeletal muscle (lane 6), aorta (lane 7), and pRSK $\text{CaCH}\beta_2$, a rabbit skeletal muscle β_2 cDNA clone (lane 8), were hybridized with a β_2 oligonucleotide, nucleotides 753–784. The PCR products were primed with β_2 oligonucleotides, nucleotides 541–560, and the complement of nucleotides 953–972.

(D) PCR products of pVDCCH(A), an α_{1D} cDNA clone (lane 1), human genomic DNA (lane 2), IMR32 cells (lane 3), skeletal muscle (lane 4), hippocampus and basal ganglia (lane 5), habenula (lane 6), and thalamus (lane 7), were hybridized with an α_{1D} oligonucleotide, nucleotides 164–187. The PCR products were primed with α_{1D} oligonucleotides, nucleotides –39 to –18, and the complement of nucleotides 201–314.

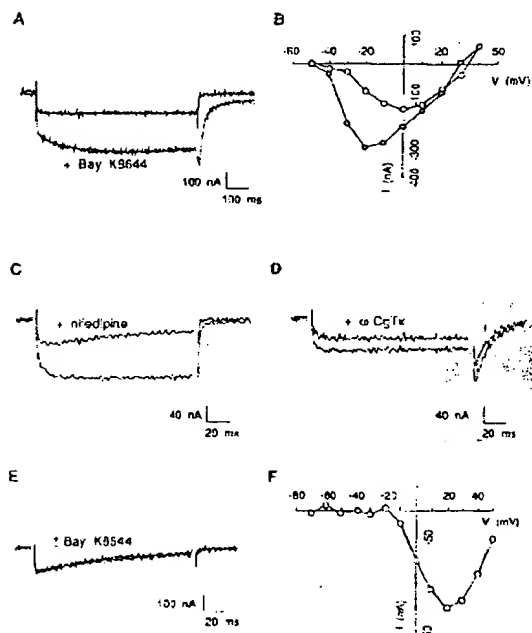

Figure 6. Functional Expression of α_{1D} , α_{2B} , and β_2 in Xenopus Oocytes

(A) I_{Ca} recorded before and after application of Bay K 8644 (1 μM) in an oocyte injected with α_{1D} , α_{2B} , and β_2 mRNAs. Test pulse, –10 mV; holding potential, –50 mV.

(B) Peak current-voltage relations before (open circles) and after (closed circles) application of Bay K 8644 for the α_{1D} , α_{2B} , and β_2 mRNA-injected cell of (A). Holding potential, –50 mV.

(C) Currents before and after (+) application of nifedipine (5 μM) in an oocyte injected with α_{1D} , α_{2B} , and β_2 mRNAs. Current traces are signal averages of three traces before and three traces after application of nifedipine. Test pulse, 0 mV; holding potential, –50 mV.

(D) Currents in the absence and presence (+) of ω -CgTx (10 μM) in an oocyte injected with α_{1D} , α_{2B} , and β_2 mRNAs. Bay K 8644 (1 μM) was present throughout. Current traces are signal averages of three traces before and three traces after application of ω -CgTx for approximately 1.5 min. Test pulse, 0 mV; holding potential, –50 mV.

(E) Currents before and after application of Bay K 8644 (1 μM) in an oocyte injected with α_{2B} and β_2 mRNAs. Superimposed current traces are signal averages of four traces before and four traces after application of Bay K 8644. Test pulse, 20 mV; holding potential, –90 mV.

(F) Peak current-voltage relation for the α_{2B} and β_2 mRNA-injected cell of (E). Holding potential, –90 mV.

although the magnitude of the current was, on average, smaller. Two of four oocytes injected with $\alpha_{10}\beta_2$ responded to Bay K 8644 application similarly to the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated currents, whereas the remaining two showed no response. Three of five oocytes coinjected with the α_{10} and α_{2b} mRNAs displayed very small currents (15–30 nA) and were unresponsive to Bay K 8644.

To ensure that the currents observed in the $\alpha_{10}\alpha_{2b}\beta_2$ -injected oocytes were mediated by the α_{10} subunit, expression of the β_2 or α_{2b} subunits alone or both together was assayed. Oocytes injected with the α_{2b} mRNA displayed no detectable I_{Ba} ($n = 5$). Surprisingly, oocytes injected with β_2 mRNA displayed I_{Ba} upon depolarization (54 ± 23 nA, $n = 5$), and $\alpha_{2b}\beta_2$ -injected oocytes displayed I_{Ba} (Figure 6E) approximately 50% larger than the I_{Ba} of β_2 -injected oocytes (81 ± 60 nA, $n = 21$). Oocytes injected with the β_2 mRNA or the α_{2b} and β_2 mRNAs together displayed I_{Ba} that typically was observed first at -30 mV and that peaked at 10 – 20 mV (Figure 6F). Macroscopically, the β_2 - and $\alpha_{2b}\beta_2$ -induced currents were indistinguishable.

In contrast to the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated currents, the β_2 and $\alpha_{2b}\beta_2$ currents showed both a significant inactivation during the test pulse and a strong sensitivity to the holding potential. The I_{Ba} observed in oocytes coinjected with α_{2b} and β_2 mRNAs usually inactivated markedly during a 140 ms pulse (Figure 6E). Changing the holding potential of oocytes coinjected with the α_{2b} and β_2 mRNAs from -90 mV to -50 mV reduced the I_{Ba} $81\% \pm 15\%$ ($n = 11$). In contrast, I_{Ba} measured in oocytes coinjected with the $\alpha_{10}\alpha_{2b}\beta_2$ mRNAs was reduced $24\% \pm 16\%$ ($n = 11$) when the holding potential was changed from -90 mV to -50 mV.

The $\alpha_{2b}\beta_2$ -mediated I_{Ba} was also pharmacologically distinct from the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated current. Oocytes coinjected with α_{2b} and β_2 mRNAs displayed I_{Ba} that was insensitive to Bay K 8644 ($n = 11$; Figure 6E). Nifedipine sensitivity was difficult to measure because of the holding potential sensitivity of both nifedipine and the $\alpha_{2b}\beta_2$ -mediated I_{Ba} . Nevertheless, two oocytes coinjected with the α_{2b} and β_2 mRNAs displayed measurable I_{Ba} (25–45 nA) when depolarized from a holding potential of -50 mV, and these currents were insensitive to nifedipine (5–10 μ M) application. The $\alpha_{2b}\beta_2$ -mediated I_{Ba} showed a sensitivity to heavy metals similar to the $\alpha_{10}\alpha_{2b}\beta_2$ -mediated current.

Discussion

Distinct Neuronal Ca^{2+} Channel Subunits Comprise a Novel DHP-Sensitive Subtype

Our results demonstrate that the α_{10} subunit mediates DHP-sensitive, high voltage-activated, long-lasting Ca^{2+} channel activity (Figure 6A). Significant functional expression in oocytes of the α_{10} subunit is dependent on the coexpression of the β_2 subunit and is enhanced by coexpression with the α_{2b} subunit. The biophysical properties of activation and inactivation kinetics and voltage sensitivity of the channel formed

by the α_{10} , α_{2b} , and β_2 subunits are generally consistent with previous characterizations of neuronal L-type Ca^{2+} channels (Bean, 1989; Hess, 1990; Swandulla et al., 1991).

Immunoprecipitation of a neuronal DHP receptor previously has revealed the presence of an α_1 , α_2 , and β subunit complex (Ahlijanian et al., 1990). As an initial step toward a detailed characterization of the multiple subtypes of neuronal voltage-dependent Ca^{2+} channels, we cloned and expressed the human neuronal α_{10} , α_{2b} , and β_2 subunits. Characterization of these clones revealed that both the α_{10} and β transcripts expressed in neuronal tissue are differentially processed. Alternatively spliced α_{10} transcripts involve at least four regions: the IS6 region reported here, the cytoplasmic loop between IS6 and IIS1 (Hui et al., 1991; data not shown), the IVS3 region, and the extracellular loop between the IVS3 and IVS4 regions (Perez-Reyes et al., 1990). In addition, a recent report described a possible form of α_{10} with a truncated carboxyl terminus, although the functional significance of this form is unknown (Hui et al., 1991). Minimally, three forms of the α_2 subunit exist (Figures 5A and 5B): α_{2a} , expressed in skeletal muscle (Ellis et al., 1988); α_{2b} , expressed in neuronal tissues; and α_{2c} , expressed in aorta. At least four forms of the β subunit also exist: β_1 , expressed in skeletal muscle; β_2 and β_3 , expressed in human brain tissue; and β_4 , detected in aorta (Figure 5C). Additional forms of the β subunit may also be expressed, as indicated by two β -specific transcripts identified in skeletal muscle (Ruth et al., 1989).

Recently, a rabbit brain α_1 subunit, designated BI, was cloned and expressed (Morl et al., 1991). Not only does this subunit differ structurally from the α_{10} subunit (Figure 2), but the biophysical and pharmacological properties of the Ca^{2+} channel, formed by coexpression of the BI subunit with the rabbit skeletal muscle α_{2a} and β_1 subunits, differ from those of the human neuronal $\alpha_{10}\alpha_{2b}\beta_2$ recombinant channel. The BI-mediated Ca^{2+} channel activity is insensitive to both DHPs and ω -CgTx and inactivates rapidly compared with the α_{10} -mediated activity. The expression in *Xenopus* oocytes of both the BI-mediated and α_{10} -mediated I_{Ba} requires the coexpression of a β subunit. Thus, two structurally and pharmacologically distinct α_1 subunits expressed in neuronal tissues require a β subunit for functional Ca^{2+} channel activity in oocytes, in contrast to the α_1 subunits expressed in cardiac (Mikami et al., 1989) and smooth muscle (Biel et al., 1990).

The α_1 subunits expressed in both cardiac and lung tissues are likely encoded by the same gene (Biel et al., 1990). This gene encodes mRNAs that direct the synthesis of DHP-sensitive Ca^{2+} channels in *Xenopus* oocytes with macroscopic biophysical properties similar to the $\alpha_{10}\alpha_{2b}\beta_2$ channel (Mikami et al., 1989; Biel et al., 1990). However, the human neuronal $\alpha_{10}\alpha_{2b}\beta_2$ DHP-sensitive channel has a current-voltage relation that is shifted by approximately -20 mV, and its tail currents are markedly prolonged after Bay K 8644 application compared with the cardiac and lung channel

types. A comparison of the single-channel properties might further distinguish these different DHP-sensitive L-type Ca^{2+} channels.

The β_2 Subunit Stimulates DHP-Insensitive I_{Ba} in *Xenopus* Oocytes

Our results suggest that the α_2 and β subunits expressed in skeletal muscle ($\alpha_{2\text{s}}$ and β_1) differ structurally (Figure 3; Figure 4; Figure 5) and possibly functionally from the α_2 and β subunits expressed in brain tissue ($\alpha_{2\text{b}}$ and β_2). *Xenopus* oocytes coinjected with the rabbit skeletal muscle $\alpha_{2\text{s}}$ and β_1 mRNAs apparently do not display I_{Ba} upon depolarization (Mori et al., 1991). This is in contrast to our observation that oocytes injected with the human neuronal β_2 mRNA alone or coinjected with the β_2 and $\alpha_{2\text{b}}$ mRNAs display significant I_{Ba} upon depolarization. Coexpression of the $\alpha_{2\text{b}}$ subunit enhances the I_{Ba} , but $\alpha_{2\text{b}}$ mRNA shows no activity when injected alone.

The Ca^{2+} channel expressed in $\alpha_{2\text{b}}\beta_2$ -injected oocytes has pharmacological and biophysical properties that resemble *Xenopus* oocyte endogenous voltage-dependent Ca^{2+} channels (Dascal et al., 1986). Similar to the skeletal muscle β_1 subunit (Ruth et al., 1989), the β_2 subunit lacks hydrophobic segments capable of forming transmembrane domains. Thus, it is unlikely that the β_2 subunit alone is forming an ion channel. It is more probable that a homologous α_1 subunit exists in oocytes comprising an endogenous Ca^{2+} channel and that the activity mediated by this α_1 subunit is enhanced by the expression of the β_2 subunit, similar to that observed for the $\alpha_{1\text{D}}$ and B1 activities. Further information concerning the structure of the endogenous *Xenopus* oocyte Ca^{2+} channel is not yet available.

The Ca^{2+} channel stimulated by the presence of the β_2 subunit may contribute an inactivating, DHP-insensitive component of I_{Ba} to the total current in $\alpha_{1\text{D}}\beta_2$ -injected oocytes, especially when recorded from strongly negative holding potentials. Recordings made from $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ -injected oocytes at different holding potentials support this possibility and indicate that such contamination can be reduced, though not necessarily eliminated, by holding at -50 mV. The DHP-insensitive β_2 -mediated current may account for the residual inactivating I_{Ba} detected in $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ -injected oocytes in the presence of nifedipine (Figure 6C).

ω -CgTx Interacts with the Neuronal DHP-Sensitive Ca^{2+} Channel

ω -CgTx blocks neuronal N-type Ca^{2+} channels irreversibly (Feldman et al., 1987; McCleskey et al., 1987). In contrast to this high affinity block, ω -CgTx blocks the $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ channel reversibly with an affinity probably in the micromolar range, as indicated by the partial block with 10 – 15 μM ω -CgTx. Although preliminary experiments indicate that the $\alpha_{2\text{b}}\beta_2$ -mediated channel may be inhibited by ω -CgTx, block of Bay K 8644-induced tail currents in $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ -injected oocytes demonstrates that ω -CgTx also interacts with the

DHP-sensitive $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ channel. Reversible block by ω -CgTx of L-type (Aosaki and Kasai, 1989), T-type (McCleskey et al., 1987), and a subclass of N-type (Plummer et al., 1989) Ca^{2+} channels has been reported. Furthermore, Ca^{2+} -dependent ATP release from elasmobranch electroplax synaptosomes is blocked reversibly by ω -CgTx with micromolar affinity (Yeager et al., 1987). It thus appears that variable affinity for ω -CgTx may be shared by several types of voltage-dependent Ca^{2+} channels. A weak block such as we have demonstrated for the $\alpha_{1\text{D}}\alpha_{2\text{b}}\beta_2$ L-type channel may account for the conflicting results reported in the literature concerning the ability of ω -CgTx to block neuronal L-type channels (McCleskey et al., 1987; Suzuki and Yoshioka, 1987; Aosaki and Kasai, 1989; Plummer et al., 1989).

Conclusion

The function of DHP-sensitive Ca^{2+} channels in skeletal and cardiac muscle has been extensively studied (Hess, 1990). In contrast, the role of the neuronal L-type Ca^{2+} channel is poorly understood (Miller, 1987). L-type Ca^{2+} channels may mediate the release of neurotransmitters from some types of neurons (Holz et al., 1988). However, functional analysis is difficult due to the mixed population of voltage-dependent Ca^{2+} channel subtypes in continuous cell lines as well as cells in primary tissues. For example, L-type Ca^{2+} channels contribute a minor fraction of the I_{Ba} detectable in the cell bodies of IMR32 cells (Carbone et al., 1990; unpublished data), PC12 cells (Plummer et al., 1989), certain sensory neurons (Aosaki and Kasai, 1989), and sympathetic neurons (Plummer et al., 1989; Jones and Jacobs, 1990). In contrast, L-type channels contribute substantial I_{Ba} in some populations of sensory neurons (Scroggs and Fox, 1991) and certain CNS neurons (Mogul and Fox, 1991; Regan et al., 1991).

Our characterization of a novel human neuronal voltage-dependent Ca^{2+} channel firmly establishes the existence of multiple subtypes of DHP-sensitive L-type Ca^{2+} channels. Furthermore, this human neuronal Ca^{2+} channel appears to have functional and pharmacological properties distinct from any other recombinant Ca^{2+} channel expressed to date. Together with the evidence for differentially processed mRNAs encoding three subunits of voltage-dependent Ca^{2+} channels, these results indicate that the molecular diversity of this ion channel class is much greater than previously proposed by traditional biophysical and pharmacological studies.

Experimental Procedures

Nomenclature

The following nomenclature is used for the α , gene family and the differentially processed α_1 and β transcripts. The structurally distinct human neuronal α , gene product described here is designated $\alpha_{1\text{D}}$ in accordance with its 96.3% deduced amino acid sequence identity to the rat brain class D sequence (Snutch et al., 1990). The α_1 gene product expressed in skeletal muscle is designated $\alpha_{1\text{S}}$; the differentially processed α_1 transcript expressed in neuronal tissues is designated $\alpha_{1\text{N}}$; the aorta α_1 tran-

script is designated α_2 . The β gene product expressed in skeletal muscle is designated β_1 ; the β transcript expressed in neuronal tissues is differentially processed to produce β_2 and β_3 transcripts. An additional β transcript expressed in aorta is designated β_4 .

cDNA Libraries

Recombinant cDNA libraries were prepared, and individual cDNA clones were characterized essentially as previously described by Ellis et al. (1988). Unless otherwise noted, the nucleotide numbers in the text refer to cDNA coding sequence. For the isolation of human neuronal α_{10} subunit cDNAs, RNA was isolated from the human neuroblastoma IMR32 cell line (ATCC #CCL127), which had been grown in 1.0 mM dibutylryl cAMP for 10 days. Four different cDNA libraries were constructed into the phage vector λ gt11: oligo(dT)-primed double-stranded cDNA, 1–3 kb size fractionated by agarose gel electrophoresis; oligo(dT)-primed double-stranded cDNA, 3–9 kb size fractionated; random-primed double-stranded cDNA, >1.8 kb; and specifically primed (nucleotides 2417–2446 of α_{10}) double-stranded cDNA, >1.5 kb. Human neuronal α_{20} subunit cDNAs were isolated from a human basal ganglia cDNA library (ATCC #37433) and a human brain stem cDNA library (ATCC #37432). Human brain β_2 and β_3 subunit cDNAs were isolated from a human hippocampus cDNA library constructed in the λ phage vector λ ZAPII (Stratagene, La Jolla, CA, #936205).

Isolation of Recombinant cDNAs Encoding Different Ca^{2+}

Channel Subunits

α_{10} Subunit

Approximately 1×10^6 recombinants of the 1–3 kb library were screened with the rabbit skeletal muscle α_1 subunit cDNA (Ellis et al., 1988). Clone $\lambda\alpha 1.36$ (nucleotides 2347–3771 of α_{10}) was isolated and characterized, and the insert was used to screen the 3–9 kb library. Clone $\lambda\alpha 1.80$ (nucleotides 1573–5958) was isolated and characterized, and the 3' portion of the insert was used to screen the random-primed library from which clone $\lambda\alpha 1.163$ (nucleotides 4690–7125) was isolated. The 5' portion of $\alpha 1.80$ was subsequently used to screen the random-primed library, resulting in the isolation of clone $\lambda\alpha 1.144$ (nucleotides –510 to 1921). The 5' portion of $\alpha 1.80$ was then used to screen the specifically primed library from which clone $\lambda\alpha 1.136$ (nucleotides 1117–2478) was isolated.

α_{20} Subunit

Human genomic α_2 clones were isolated to use as α_2 -specific probes of human neuronal cDNA libraries. A rabbit skeletal muscle α_2 cDNA fragment, clone SkMCaCh2.2, comprising nucleotides 43–272 (Ellis et al., 1988), was used to identify and clone two α_2 -specific, human genomic EcoRI fragments, HGCaCh2.20 (3.5 kb) and HGCaCh2.9 (3.0 kb). Restriction mapping and DNA sequencing revealed that HGCaCh2.20 contains an 82 bp exon (nucleotides 96–177 of the human α_{20} coding sequence) and that HGCaCh2.9 contains 105 bp of an exon (nucleotides 178–282 of the coding sequence). These restriction fragments were used to screen the human basal ganglia cDNA library. HBCaCh2.1 was isolated (nucleotides –6 to 1129) and used to screen the human brain stem cDNA library. Two clones were isolated, HBCaCh2.5 (nucleotides –34 to 1128) and HBCaCh2.8 (nucleotides 680–1528 followed by 1600 nucleotides of intervening sequence). HBCaCh2.8 was used to rescreen the brain stem library and to isolate HBCaCh2.11 (nucleotides 845–3566).

β_2 and β_3 Subunits

A rabbit skeletal muscle β_1 subunit cDNA fragment (Ellis et al., 1988; Ruth et al., 1989) was used to screen the human hippocampus cDNA library. Two clones, $\lambda\beta 1$ and $\lambda\beta 4$, were isolated that appear to encode alternative splice products of the human β subunit transcript expressed in the brain, β_2 and β_3 , respectively. $\lambda\beta 1$ begins at nucleotides 69 and extends 107 nucleotides beyond the translation stop codon, encoding 1367 nucleotides of coding sequence. $\lambda\beta 1$ also contains a 448 nucleotide intron between nucleotides 1146 and 1147 of the coding sequence. $\lambda\beta 4$ begins at nucleotide 246 of the coding sequence and diverges from β_2 at nucleotide 1333 as described in the Results. $\lambda\beta 1$ was used to

rescreen the hippocampus cDNA library from which clone $\lambda\beta 1.18$ was isolated, characterized, and determined to encode nucleotides 1–325 of the β_2 coding sequence.

PCR Analysis

PCR analyses were performed essentially as described by Innis et al. (1990). IMR32 cell cytoplasmic RNA was prepared as described by Ausubel et al. (1988). For the analysis of the series of 5' methionine codons in the α_{10} cDNA, four oligonucleotide primers were synthesized (numbered in the 5' to 3' orientation): (1) nucleotides –39 to –18, beginning 39 nucleotides 5' of the first methionine codon; (2) nucleotides 58–87; (3) nucleotides 164–187; and (4) nucleotides 314–291. The oligonucleotide pairs (1, 4), (2, 4), and (3, 4) were used to prime PCR assays of cytoplasmic RNA and human genomic DNA. PCR amplification of human genomic DNA and IMR32 cytoplasmic RNA with oligonucleotide pairs (2, 4) and (3, 4) gave the predicted size product (260 and 150 bp, respectively). The cytoplasmic RNA assayed with the pair (1, 4) gave the predicted size product (350 bp); a PCR product of genomic DNA primed with the pair (1, 4) was not detected. The lack of a PCR product primed with pair (1, 4) on genomic DNA suggested the possible presence of an intron between oligonucleotides 1 and 2 and indicated that the positive results with the RNAs could not be due to genomic DNA contamination of the RNA preparations. The cytoplasmic RNA PCR product of the (1, 4) oligonucleotide pair was cloned and sequenced.

Construction of Full-Length cDNAs

α_{10} Subunit

pVDCIII(A) was constructed using $\alpha 1.144$ (nucleotides –184 to 1222), $\alpha 1.136$ (nucleotides 1222–2157), $\alpha 1.80$ (nucleotides 2157–4784), and $\alpha 1.163$ (nucleotides 4784–7125). PCR analysis of the α_{10} transcript revealed that $\alpha 1.80$ contained a 148 nucleotide deletion (nucleotides 2474–2621). To correct this deletion, PCR was performed on IMR32 RNA, and the AccI–BglII fragment (nucleotides 2254–3380) was isolated and used to replace the $\alpha 1.80$ fragment.

α_{20} Subunit

pHBCaCh2(A) was constructed using HBCaCh2.5 (nucleotides –34 to 1027) and HBCaCh2.11 (nucleotides 1027–3566).

β_2 Subunit

To construct pHBCaCh β_2 , RBS(A), the 448 nucleotide intron of $\lambda\beta 1$ first was deleted via site-directed mutagenesis (Sambrook et al., 1989). $\lambda\beta 1$ was subcloned into M13mp19. The mutagenic oligonucleotide was the sense strand of β_2 encoding nucleotides 1126–1165. The final construct was designated p $\beta 1$ (–). pHBCaCh β_2 , RBS(A) then was constructed using $\lambda\beta 1.18$ (nucleotides 1–282) and p $\beta 1$ (–) (nucleotides 282–1547). The 5' untranslated sequence in $\lambda\beta 1.18$ was replaced with an efficient ribosomal-binding site so that the sequence reads 5'-CAATTC (EcoRI) ACCACC (ribosomal-binding site) ATC (start codon) ... -3'. Each α_{10} , α_{20} , and β_2 full-length construct was subcloned into pcDNA1 (Invitrogen, San Diego, CA).

Expression Studies in *Xenopus* Oocytes

In vitro transcripts of human neuronal α_{10} , α_{20} , and β_2 subunit cDNAs were synthesized according to the instructions of the mCAP mRNA Capping Kit (Stratagene, La Jolla, CA, #200350). Each plasmid first was linearized by restriction digestion: pVDCIII(A) with XhoI, pHBCaCh2(A) with XhoI, and pHBCaCh β_2 , RBS(A) with EcoRV. T7 RNA polymerase was used to transcribe each cDNA. *Xenopus laevis* oocytes were dissociated and defolliculated by collagenase treatment and maintained in 100 mM NaCl, 2 mM KCl, 1.8 mM CaCl_2 , 1 mM MgCl_2 , 5 mM HEPES (pH 7.6), 20 $\mu\text{g}/\text{ml}$ ampicillin, and 25 $\mu\text{g}/\text{ml}$ streptomycin at 19°C–25°C for 2–5 days after injection and prior to recording. Oocytes were injected with 6 ng of each in vitro synthesized mRNA species per cell in a volume of 50 nl and were assayed by the two-electrode voltage-clamp method (Dascal, 1987) using the pClamp (Axon Instruments) software package in conjunction with a Labmaster 125 kHz data acquisition interface (Scientific Solutions) to generate voltage commands and to acquire and analyze data. Current signals were digitized at 1–5 kHz and filtered appropriately. In

was recorded in a solution intended to minimize currents carried through K^+ , Cl^- , or Na^+ channels (Snutch et al., 1990): 40 mM $BaCl_2$, 36 mM tetraethylammonium chloride, 2 mM KCl , 5 mM 4-aminopyridine, 0.15 mM nitrofluoric acid, 5 mM HEPES (pH 7.6). Currents were leak subtracted by the P/n method provided in pClamp, where n was -4 or -6. Drugs were applied directly into the 60 μ l bath while the perfusion pump was turned off. Bay K 8644 and nifedipine were prepared fresh from stock solutions (in dimethyl sulfoxide) and diluted into the bath solution. The dimethyl sulfoxide concentration of the final drug solutions in contact with the cell never exceeded 0.1%. Control experiments showed that 0.1% dimethyl sulfoxide had no effect on membrane currents. ω -CgTx was prepared in a 15 mM $BaCl_2$ bath solution plus 0.1% cytochrome C (Sigma) (Feldman et al., 1987) to serve as a carrier protein. Control experiments showed that cytochrome C had no effect on currents. Before and during ω -CgTx application, test pulses were recorded at 20 s intervals from the holding potential (-90 mV or -50 mV) to the peak I_{Ca} (-10 mV to 10 mV). To reduce the inhibition of ω -CgTx binding by divalent cations (McCleskey et al., 1987), recordings were made in 15 mM $BaCl_2$, 73.5 mM tetraethylammonium chloride, and the remaining ingredients identical to the 40 mM Ba^{2+} recording solution.

(57) **ABSTRACT**

A DNA molecule encoding a novel isoform of the human T-type low voltage activated calcium channel (alpha1G-c) has been cloned and characterized. The biological and structural properties of this protein is disclosed, as is the amino acid and nucleotide sequence.

Mibefradil blocks human
alpha 1G calcium channels
expressed in oocytes

1

DNA ENCODING HUMAN ALPHA1G-C T-TYPE CALCIUM CHANNEL

BACKGROUND OF THE INVENTION

Voltage activated calcium channels play important roles including neuroexcitation, neurotransmitter and hormone secretion, and regulation of gene transcription through Ca-dependent transcription factors. Their functions depend in part on their cellular localization and their gating properties (characteristics of their opening, inactivation, deactivation, and recovery from inactivation). Five general classes of voltage activated calcium channels have been observed in various neuronal and non-neuronal tissues. The complement of channel subunits and the subcellular localization of the expressed voltage activated calcium channels determine the functional cellular properties.

Diversity of Voltage-gated Ca Channels Fall into Two Major Categories: Low Voltage Activated (LVA) and High Voltage Activated (HVA)

A conserved general structure for all cloned voltage-gated calcium channel alpha subunits (the pore-forming subunit) has been identified. It consists of 4 domains with homology to the domains present in voltage-gated K and Na channels. Each domain contains 6 membrane spanning regions (S1-S6) and a pore region (P) located between S5 and S6. The extracellular loops are generally very short; intracellular loops contain sites that are modulated by phosphorylation and can interact with other effectors. However, there are notable differences in the lengths of the S5-S6 loop of domain I and the intracellular loop between domains I and II among alpha subunits.

Different calcium channels are best distinguished by their pharmacological profiles since their electrophysiological properties differ depending on the cell type or tissue in which they are expressed, presumably because of modulation by cellular proteins, for instance kinases, and also auxiliary calcium channel subunits.

The HVA channel classes are thought to be composed of at least 3 or 4 different subunits: $\alpha 1$ (which contains the pore), beta (β) and $\alpha 2\delta$. In skeletal muscle a γ subunit also co-precipitates with the skeletal channel complex. Recently two gamma-like subunits have been cloned from brain—one of which is the gene mutated in the stargazer mutant mouse (Black et al., 1999; Lettis et al., 1998). The subunit composition has been proved for only the skeletal L-type ($\alpha 1$ $\alpha 2\delta$ β γ) and brain N-type ($\alpha 1$ $\alpha 2\delta$ β) channels (Perez-Reyes and Schneider, 1995). These channels generally require large membrane depolarizations for activation (~30 mV from the resting potential (RP)). Four classes of HVA calcium channels have been identified on the basis of electrophysiological, pharmacological and molecular data. These classes include L-type (encoded by at least 4 genes (including a $\alpha 1$ subunits $\alpha 1S$ (skeletal muscle), $\alpha 1C$, $\alpha 1D$ (neuroendocrine), and $\alpha 1F$ (retinal)), N-type ($\alpha 1B$; (Williams et al., 1992)), P/Q-type ($\alpha 1A$) and R-type (encoded by at least the $\alpha 1E$ gene).

HVA $\alpha 1$ families are strongly affected by co-expression of the cytoplasmically localized β subunit, particularly the expression levels of functional cell surface channels and the electrophysiological response of the channel (i.e., kinetics). β subunits interact with a specific sequence in the I-II intracellular loop to increase the number of functional channels and alter the activation and inactivation properties of the channel complex (Furukawa et al., 1998). There are at least 4 β genes that are alternatively spliced ($\beta 1a$ -c; $\beta 2a$ -c; $\beta 3$; $\beta 4$; (Perez-Reyes and Schneider, 1995)); the effect of each of these β s on $\alpha 1$ function appears to depend on the $\alpha 1$

2

class. Interestingly, mutants in β (Cch $\beta 4$) produce ataxia and seizures in the lethargic (lh) mouse (Burgess et al., 1997). $\alpha 2\delta$ subunits also modulate $\alpha 1$ function and the known gene co-segregates with malignant hyperthermia phenotype in certain families (Iles et al., 1994).

The physiological roles of HVA channels depend on subcellular location of the channel and tissue type. Subcellular location varies among tissues but have been shown to be important in neurotransmitter and hormone release, action potential duration, excitation-contraction coupling in muscle cells, and gene expression (Miller, 1987).

There are at least three genes in the T-type family of LVA calcium channels ($\alpha 1G$, $\alpha 1H$, and $\alpha 1I$) (Perez-Reyes, 1998). Their structure differs from that of the HVA channels in a number of important ways. The I-II intracellular linker is much longer (~400 amino acids) than that of the known HVA channels. The Domain I S5-P extracellular linker is longer than that of the HVA channels and may be a good target for drug interactions with this channel. β does not appear to be associated with $\alpha 1$ in this class and they lack the canonical sequence that is known to be crucial for beta subunit binding (Lambert et al., 1997; Leuranguer et al., 1998). Anti-sense experiments directed against all known beta's show a decrease in the expression of HVA calcium channels but not LVA calcium channels in nodose ganglion neurons (Lambert et al., 1997).

Other proteins or cellular environments may be required for robust T-channel expression since $\alpha 1G$ expressed in oocytes or HEK293 cells produces dramatically different current magnitudes in these two cell types (Perez-Reyes, 1998).

T-type calcium currents have been observed in vivo in many cell types in the peripheral and central nervous systems including thalamus, inferior olive, cerebellar Purkinje cells, lateral habenular cells, dorsal horn neurons, sensory neurons (DRG, nodose), cholinergic forebrain neurons, hippocampal interneurons, CA1, CA3 dentate gyrus pyramidal cells, basal forebrain neurons, amygdaloid neurons (Talley et al., 1999). T-type channels are prominent in the soma and dendrites of neurons that reveal robust Ca-dependent burst firing behaviors such as the thalamic relay neurons and cerebellar Purkinje cells (Huguenard, 1996).

Physiological Roles and Therapeutic Areas

T-type calcium channels are involved in the generation of low threshold spikes to produce burst firing (Huguenard, 1996). These channels differ from HVA channels in that they have some probability of opening at the resting membrane potential. Because their steady state inactivation curve is shifted toward negative voltages compared to HVA channels (i.e., half the channels are not inactivated and are able to be opened by a depolarizing voltage step at voltages more negative than the resting membrane potential (RP)), there is a window current near the RP (i.e., a portion of the T-channels are open at RP). Low threshold spikes and rebound burst firing is prominent in neurons from inferior olive, thalamus, hippocampus and neocortex (Huguenard, 1996).

T-type channels promote oscillatory behavior which has important consequences for epilepsy. The ability of a cell to fire low threshold spikes is critical in the genesis of oscillatory behavior and increased burst firing (groups of action potentials separated by about 50-100 ms). T-type calcium channels are thought to play a significant role in absence epilepsy, a type of generalized non-convulsive seizure. The evidence that voltage-gated calcium currents contribute to the epileptogenic discharge, including seizure maintenance and propagation includes 1) a specific enhancement of

T-type currents in the reticular thalamic (nRT) neurons which are hypothesized to be involved in the genesis of epileptic seizures in a rat genetic model (GAERS) for absence epilepsy (Tsakiridou et al., 1995); 2) antiepileptics against absence petit mal epilepsy (ethosuximide and dimethadione) have been shown at physiologically relevant doses to partially depress T-type currents in thalamic (ventrobasal complex) neurons (Coulter et al., 1989; Kostyuk et al., 1992); and 3) T-type calcium channels underlie the intrinsic bursting properties of particular neurons that are hypothesized to be involved in epilepsy (nRT, thalamic relay and hippocampal pyramidal cells) (Huguenard, 1996). The rat $\alpha 1G$ is highly expressed in thalamocortical relay cells (TCs) which are capable of generating prominent Ca^{2+} -dependent low-threshold spikes (Talley et al., 1999).

T-type channels play a critical role in thalamic oscillations and cortical synchrony, and their involvement has been directly implicated in the generation of cortical spike waves that are thought to underlie absence epilepsy and the onset of sleep (McCormick and Bal, 1997). Oscillations of neural networks are critical in normal brain function such during sleep-wave cycles. It is widely recognized that the thalamus is intimately involved in cortical rhythmogenesis. Thalamic neurons most frequently exhibit tonic firing (regularly spaced spontaneous firing) in awake animals, whereas phasic burst firing is typical of slow-wave sleep and may account for the accompanying spindling in the cortical EEG. The shift to burst firing occurs as a result of activation of a low threshold Ca^{2+} spike which is stimulated by synaptically mediated inhibition (i.e., activated upon hyperpolarization of the RP). The reciprocal connections between pyramidal neurons in deeper layers of the neocortex, cortical relay neurons in the thalamus, and their respective inhibitory interneurons are believed to form the elementary pacemaking circuit.

T-type channels contribute to synaptic potentiation at the postsynaptic level since small changes in membrane potential (V_m) (either depolarizations (epsp; excitatory postsynaptic potentials) or hyperpolarizations (ipsp; inhibitory postsynaptic potentials); anode break excitation or rebound burst firing) can open T-type calcium channels. At the hyperpolarized V_m during the ipsp more T-type channels become available to open (they have recovered from inactivation) so that upon repolarization to the RP, a larger proportion of T channels are opened and this produces anode break excitation, a robust rebound burst firing as the low threshold Ca spike reaches threshold for Na channel activation and action potential generation. A burst of action potentials ride on top of the Ca -dependent depolarization. This phenomenon is particularly prominent in reticular thalamic neurons (Huguenard, 1996).

T-type channels can be involved in transmitter release. In cells where T-channels are located at the presynaptic terminal, they promote neurotransmitter release (Ahnert-Hilger et al., 1996; Arnoult et al., 1997)

T-type channels contribute to spontaneous fluctuations in intracellular Ca concentrations $[Ca]$. They are important in pacemaker activity and therefore heart rate in the heart, and in vesicle release from non-excitable cells (Ertel et al., 1997).

T-type calcium currents are expressed differentially in different subpopulations of adult rat dorsal root ganglion (DRG) neurons. T-type currents were present at moderate densities in small diameter Type 1 and 3 cells, the former having TTX-resistant Na currents, long duration action potentials and capsaicin sensitivity (consistent with a C type

nociceptive neuron) and the latter having short action potential durations, no capsaicin sensitivity (consistent with a A δ nociceptive or A α/β neurons) (Cardenas et al., 1995). There appear to be different types of LVA currents expressed in adult rat sensory neurons based on differential sensitivity to nM concentrations of nimodipine (Formenti et al., 1993). Because of the role of the T type calcium channel in contributing to near threshold membrane excitability, selective suppression of the T channels will decrease neuronal hyperexcitability (painful neuropathies) and raise the threshold for the perception of pain (central pain syndromes).

A specific blocker for T-type calcium channels in the pacemaker cells and conduction fibers in the heart might demonstrate "pure" bradycardic (slowing the heart rate) properties since T channels are not usually present in the ventricular myocytes of man. Drugs that block the T-type channel in specific conformational states might allow treatment of tachycardia (by decreasing the heart rate) while having little effect on the inotropic properties of the normal heart (Rousseau et al., 1996). A cardiomyopathic disease (genetic Syrian hamster model) is a result of Ca -overload due to an increased expression of T-type calcium channels in ventricular myocytes (Sen and Smith, 1994). There are increased T-type currents in atrial myocytes from adult rats with growth hormone-secreting tumors (Xu and Best, 1990). A specific T-type calcium channel blocker would act as a cardioprotectant in these cases.

T-type channels in adrenal zona fasciculata cells of the adrenal cortex have been shown to modulate cortisol secretion (Enyeart et al., 1993). Cortisol is the precursor for glucocorticoids and prolonged exposure to glucocorticoids causes breakdown of peripheral tissue protein, increased glucose production by the liver and mobilization of lipid from the fat depots. Furthermore, individuals suffering from anxiety and stress produce too high levels of glucocorticoids and drugs that would regulate these levels are sought after (eg., antagonists to CRF).

T-type calcium channels may be involved in release of nutrients from testis Sertoli cells. T-type calcium channels are expressed on immature rat Sertoli cells (Lalevee et al., 1997). Sertoli cells are testicular cells that are thought to play a major role in sperm production. The intimate juxtaposition of the developing germ cells with the Sertoli cells suggests the latter play a role in supporting and nurturing the gametes. Sertoli cells secrete a number of proteins including transport proteins, hormones and growth factors, enzymes which regulate germinal cell development and other biological processes related to reproduction (Griswold, 1988). They secrete the peptide hormone inhibin B, an important negative feedback signal to the anterior pituitary. They assist in spermiogenesis (the final detachment of the mature spermatozoa from the Sertoli cell into the lumen) by releasing plasminogen activator which produces proteolytic enzymes. While the role of T channels is not known, they may be important in the release of nutrients, inhibin B, and/or plasminogen activator.

Inhibition of T-type calcium channels in sperm during gamete interaction inhibits zona pellucida-dependent Ca^{2+} elevations and inhibits acrosome reactions, thus directly linking sperm T-type calcium channels to fertilization (Arnoult et al., 1996).

T-type calcium channels have also been implicated in cellular growth and proliferation, particularly in the cardiovascular system (Katz, 1999; Lijnen and Petrov, 1999; Richard and Nargeot, 1998; Wang et al., 1993).

Tremor can be controlled through the basal ganglia and the thalamus, regions in which T type calcium channels are

strongly expressed (Talley et al., 1999). T-type calcium channels have been implicated in the pathophysiology of tremor since the anti-epileptic drug ethosuximide is used for treating tremor, in particular, tremor associated with Parkinson's disease, essential tremor, or cerebellar disease (U.S. Pat. No. 4,981,867; D. A. Prince).

Pharmacology

There are no known specific blockers of the T-type class of calcium channel. There are ions (ex. Ni^{2+}) that are more effective toward blocking T-type calcium channels vs. HVA channels, and there are a few drugs that block T channels with higher affinity than HVA channels. A number of pharmacological blockers have differential effects on T type calcium currents expressed in different cell types (see Table 1 from (Todorovic and Lingle, 1998)), however there is a diversity of pharmacological profiles of T-type currents. The differential sensitivity of the currents to antagonists may be due to different subunit structure (Perez-Reyes, 1998) as well as cellular environments. T-type calcium channel alpha subunit genes, like the genes for HVA channels, reveal alternative splicing (Lee et al., 1999 *Biophys J* 76:A408). Extracellular and intracellular loops of individual T-type calcium channel clones show marked diversity amongst themselves and even less homology to HVA channels.

Mibefradil ((1S,2S)-2-[2-[[3-(1H-benzimidazol-2-yl)propyl]methyl-amino]ethyl]-6-fluoro-1-isopropyl-1,2,3,4-tetrahydronaphthalen-2-yl methoxyacetate) blocks the T-type calcium channel by preferentially interacting with inactivated state. Thus, in a cell type with a relatively low RP (-50 mV) such as the smooth muscle cells, nearly all T channels will be blocked by mibefradil, whereas in cells with a very negative RP such as cardiac myocytes most of the T channels are not inactivated and therefore will not be blocked by mibefradil (Bezprozvanny and Tsien, 1995). Mibefradil had a complex blocking action on the mouse alpha1G when applied from holding potentials of -60 and could best be fit by fitting to 2 populations of sites (Klugbauer et al., 1999). The high affinity component was reduced at -100 mV. The most prominent (low affinity) site had an IC_{50} value for mibefradil of ~ 400 nM.

Ethosuximide is used to treat absence epilepsy and at therapeutically relevant concentrations (0.25 – 0.75 mM) (Sherwin, 1989) partially blocks T-type currents in some preparations (Coulter et al., 1989). Ethosuximide has different affinities for T-type calcium channels in different tissues. The majority of T type currents from guinea pig or rat ventrobasal thalamic neurons revealed an IC_{50} for mibefradil of ~ 500 μM and a maximal block of $\sim 40\%$ block at 1 mM (Coulter et al., 1989). Interestingly, there was no effect of ethosuximide on T-currents in 25% of the TCs tested (Coulter et al., 1989). In hippocampal CA3 neurons, all components of the LVCC were insensitive to ethosuximide at 250 μM or 1 mM. If T-type calcium channels underlie the LVCC in these cells, then the drug had no effect on these T-type calcium channels (Avery and Johnston, 1996). The T-type calcium channels from dorsal root ganglion neurons from one-day-old rats have higher affinity for ethosuximide than thalamic neurons (Kd for T-current is 7 μM vs 15 μM for L-type current) with a maximal block of 100% (Kostyuk et al., 1992). The human alpha1H is insensitive to ethosuximide (Williams et al., WO 9928342; Williams et al., 1999).

Ni^{2+} is thought to act not only at the pore region but also at another unknown location on the channel protein (Zamponi et al., 1996). The mouse alpha1G has a very low sensitivity to Ni^{2+} as opposed to other T-type channels (Klugbauer et al., 1999). The human alpha1H expressed in oocytes has an IC_{50} for Ni^{2+} of about 6 μM (Williams et al., WO 9928342).

Amiloride, an antagonist at numerous receptors, channels and exchangers, is a low affinity antagonist at T-type calcium channels. There are noted differences in sensitivity of T currents to amiloride (Todorovic and Lingle, 1998). The effects of amiloride are highly variable depending on the cell type, with EC_{50} 's ranging from 50 to >1000 μM , suggesting that different levels of T-type channel expression in different cells or different channel complexes within different cells (Huguenard, 1996). For instance, the human alpha1H expressed in oocytes has an IC_{50} for amiloride of about 20 μM (Williams et al., WO 9928342).

NPPB (5-Nitro-2-(3-phenylpropylamino)benzoic acid) has been used to isolate N-type calcium channels (Stea et al., 1999) and was used in studies on the present invention to isolate T-type calcium channels. However, we found NPPB blocked alpha1G-c currents. NPPB has been shown to block voltage-sensitive calcium currents (Kirkup et al., 1996), and, more specifically, L-type calcium currents (Doughty et al., 1998). Interestingly, NPPB reduced the Ca^{2+} resting current and altered the spike frequency of isolated cockroach dorsal unpaired median neurons (Heine and Wicher, 1998). The resting calcium current may be mediated by a T-type calcium channel, but this has yet to be confirmed.

SUMMARY OF THE INVENTION

A DNA molecule encoding a novel isoform of the human T-type low voltage activated calcium channel (alpha1G-c) has been cloned and characterized. The biological and structural properties of this protein is disclosed, as is the amino acid and nucleotide sequence. The recombinant protein is useful to identify modulators of the alpha1G-c calcium channel. Modulators identified in the assays disclosed herein are useful as therapeutic agents and are candidates for the treatment disorders that are mediated by human alpha1G-c activity. Such activities that may be mediated by human alpha1G-c include, epilepsy, schizophrenia, depression, sleep disorders, stress, endocrine disorders, respiratory disorder, peripheral muscle disorders, muscle excitability, Cushing's disease, fertilization, contraception, disorders involving neuronal firing regulation, respiratory disorders, hypertension, cardiac rhythm, potentiation of synaptic signals, improving arterial compliance in systolic hypertension, vascular tone such as by decreasing vascular swelling, cellular growth (protein synthesis, cell differentiation, and proliferation), cardiac hypertrophy, cardiac fibrosis, atherosclerosis, cardiovascular disorders, including but not limited to: myocardial infarct, cardiac arrhythmia, heart failure and angina pectoris. The recombinant DNA molecules, and portions thereof, are useful for isolating homologues of the DNA molecules, identifying and isolating genomic equivalents of the DNA molecules, and identifying, detecting or isolating mutant forms of the DNA molecules.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1, Panel A, Panel B and Panel C—The nucleotide sequence of coding region of human calcium channel alpha1G-c is shown (6822 bp including the stop codon).

FIG. 2, Panel A, Panel B and Panel C—The nucleotide sequence of human calcium channel alpha1G-c is shown including 511 bp 5' UT and 397 bp 3'UT.

FIG. 3—The amino acid sequence of human calcium channel alpha1G-c is shown (2273 amino acids).

FIG. 4—Functional expression of human calcium channel alpha1G-c in *Xenopus* oocytes is shown: activation by

depolarizing voltage steps (a,b) and steady state inactivation (c,d). a) An oocyte bathed in 40 mM BaCl₂ saline was challenged with a depolarizing voltage protocol from a holding potential of -100 mV. 40 msec test pulses were applied from -70 to -20 mV in increments of 10 mV. b) The current-voltage relationship obtained from 9 oocytes bathed in ND96. Currents activated near -60 mV and reversed sign near +30 mV. Peak currents were elicited by steps to about -30 mV. c) The voltage-dependence of inactivation of an oocyte bathed in 40 mM BaCl₂ was determined using a standard voltage protocol. Four sec voltage steps to -100 to -45 mV (in increments of 5 mV) were followed by a 5 msec step to -100 mV, followed by a step to -30 mV. The currents elicited at -30 mV are shown after the positive-going capacitive transient. The prepulse voltage that inactivated half the channels ($V_{0.5}$) was about -70 mV. d) The voltage dependence of inactivation is shown for oocytes bathed in ND96 (n=9 experiments).

FIG. 5—Pharmacological characterization of human alpha1G-c expressed in *Xenopus* oocytes: dose dependent block by mibefradil. The responses to the indicated concentrations of mibefradil were bath applied to oocytes expressing human calcium channel alpha1G-c cRNA. Shown are 1-3 concentrations tested on 7 individual oocytes. The IC₅₀ was 2.5 μ M with a 95% confidence interval of 1.3 to 4.9 μ M. Oocytes were bathed in ND96.

DETAILED DESCRIPTION

The present invention relates to DNA encoding human calcium channel alpha1G-c that was isolated from a human thalamus cDNA library. Human calcium channel alpha1G-c, as used herein, refers to protein that can specifically function as a low voltage activated calcium channel.

The sequence presented in this invention is a homolog of the rat alpha1G accession # AF027984 (Perez-Reyes et al., 1998), and is similar to the human alpha1G "a" isoform (accession # AF126966) with the exception that the sequence presented herein contains a 23 amino acid insert in the second intracellular loop between domains I and II that is missing in both sequences. The 23 amino acid insert contains a putative CKII phosphorylation site at S971. This 23 amino acid insert is 91 and 87% identical to homologous sequences in rat (AF125161) and mouse (AJ012569), respectively, two proteins otherwise dissimilar to human alpha1G-c since they contain an insert at alpha1G amino acid 1575. The putative casein kinase II phosphorylation site in the human alpha1G-c insert is not conserved in the equivalent rat or mouse sequences. The previously described human full length cDNA (AF126966) produces functional channels (Monteil, et al., 1999 Cloning and molecular characterization of $\alpha 1G$ and $\alpha 1I$ isoforms of human T-type Ca²⁺ channels. *Biophys. Abst.* A408) but a complete description of its functional and structural characteristics has not been reported. The present invention is thus the first report, to our knowledge, of a detailed characterization of the human alpha1G-c T-type calcium channel. There are 2 partial human sequences that are identical to regions of the present invention submitted by E. Perez-Reyes (AF029229; AF029228). AF029228 begins at alpha1G-c at amino acid 1186 and ends at amino acid 1504; AF029229 begins at amino acid 1827 and ends at the TGA stop codon.

The complete amino acid sequence of human calcium channel alpha1G has been previously described, however, the present invention is a novel isoform that was not previously known. This is the first reported cloning of a full length DNA molecule encoding the "c" isoform of the

human calcium channel alpha1G. It is predicted that a wide variety of cells and cell types will contain the described channel.

Other cells and cell lines may also be suitable for use to isolate human calcium channel alpha1G-c. Selection of suitable cells may be done by screening for human calcium channel alpha1G-c activity in whole cells or cell extracts. Human calcium channel alpha1G-c activity can be monitored by direct measurement of a low depolarizing voltage-induced Ca²⁺ influx or Ca currents through the human calcium channel alpha1G-c. Cells that possess human calcium channel alpha1G-c activity in this assay may be suitable for the isolation of human calcium channel alpha1G-c DNA or mRNA.

Any of a variety of procedures known in the art may be used to molecularly clone human calcium channel alpha1G-c. These methods include, but are not limited to, direct functional expression of the human calcium channel alpha1G-c genes following the construction of a human calcium channel alpha1G-c -containing cDNA library in an appropriate expression vector system. Another method is to screen human calcium channel alpha1G-c -containing cDNA library constructed in a bacteriophage or plasmid shuttle vector with a labelled oligonucleotide probe designed from the amino acid sequence of the human calcium channel alpha1G-c insert. An additional method consists of screening a human calcium channel alpha1G-c-containing cDNA library constructed in a bacteriophage or plasmid shuttle vector with a partial cDNA encoding the human calcium channel alpha1G-c protein. This partial cDNA is obtained by the specific PCR amplification of human calcium channel alpha1G-c DNA fragments through the design of degenerate oligonucleotide primers from the amino acid sequence of the purified human calcium channel alpha1G-c protein.

Another method is to isolate RNA from human calcium channel alpha1G-c-producing cells and translate the RNA into protein via an in vitro or an in vivo translation system. The translation of the RNA into a peptide a protein will result in the production of at least a portion of the human calcium channel alpha1G-c protein which can be identified by, for example, immunological reactivity with an anti-human calcium channel alpha1G-c antibody or by biological activity of human calcium channel alpha1G-c protein. In this method, pools of RNA isolated from human calcium channel alpha1G-c-producing cells can be analyzed for the presence of an RNA that encodes at least a portion of the human calcium channel alpha1G-c protein. Further fractionation of the RNA pool can be done to purify the human calcium channel alpha1G-c RNA from non-human calcium channel alpha1G-c RNA. The peptide or protein produced by this method may be analyzed to provide amino acid sequences, which in turn are used to provide primers for production of human calcium channel alpha1G-c cDNA, or the RNA used for translation can be analyzed to provide nucleotide sequences encoding human calcium channel alpha1G-c and produce probes for this production of human calcium channel alpha1G-c cDNA. This method is known in the art and can be found in, for example, Maniatis, T., Fritsch, E. F., Sambrook, J. in *Molecular Cloning: A Laboratory Manual*, Second Edition, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, N.Y. 1989.

It is readily apparent to those skilled in the art that other types of libraries, as well as libraries constructed from other cells or cell types, may be useful for isolating human calcium channel alpha1G-c-encoding DNA. Other types of libraries include, but are not limited to, cDNA libraries derived from other cells and genomic DNA libraries that include YAC (yeast artificial chromosome) and cosmid libraries.

It is readily apparent to those skilled in the art that suitable cDNA libraries may be prepared from cells or cell lines which have human calcium channel $\alpha 1G$ -c activity. The selection of cells or cell lines for use in preparing a cDNA library to isolate human calcium channel $\alpha 1G$ -c cDNA may be done by first measuring cell associated human calcium channel $\alpha 1G$ -c activity using the measurement of calcium regulated biological activity.

Preparation of cDNA libraries can be performed by standard techniques well known in the art. Well known cDNA library construction techniques can be found for example, in Maniatis, T., Fritsch, E. F., Sambrook, J., *Molecular Cloning: A Laboratory Manual*, Second Edition (Cold Spring Harbor A Laboratory, Cold Spring Harbor, N.Y., 1989).

It is also readily apparent to those skilled in the art that DNA encoding human calcium channel $\alpha 1G$ -c may also be isolated from a suitable genomic DNA library. Construction of genomic DNA libraries can be performed by standard techniques well known in the art. Well known genomic DNA library construction techniques can be found in Maniatis, T., Fritsch, E. F., Sambrook, J. in *Molecular Cloning: A Laboratory Manual*, Second Edition (Cold Spring Harbor Laboratory, Cold Spring Harbor, N.Y., 1989).

In order to clone the human calcium channel $\alpha 1G$ -c gene by the above methods, the amino acid sequence of human calcium channel $\alpha 1G$ -c may be necessary. To accomplish this, human calcium channel $\alpha 1G$ -c protein may be purified and partial amino acid sequence determined by automated sequencers. It is not necessary to determine the entire amino acid sequence, but the linear sequence of two regions of 6 to 8 amino acids from the protein is determined for the production of primers for PCR amplification of a partial human calcium channel $\alpha 1G$ -c DNA fragment.

Once suitable amino acid sequences have been identified, the DNA sequences capable of encoding them are synthesized. Because the genetic code is degenerate, more than one codon may be used to encode a particular amino acid, and therefore, the amino acid sequence can be encoded by any of a set of similar DNA oligonucleotides. Only one member of the set will be identical to the human calcium channel $\alpha 1G$ -c sequence but will be capable of hybridizing to human calcium channel $\alpha 1G$ -c DNA even in the presence of DNA oligonucleotides with mismatches. The mismatched DNA oligonucleotides may still sufficiently hybridize to the human calcium channel $\alpha 1G$ -c DNA to permit identification and isolation of human calcium channel $\alpha 1G$ -c encoding DNA. DNA isolated by these methods can be used to screen DNA libraries from a variety of cell types, from invertebrate and vertebrate sources, and to isolate homologous genes.

Purified biologically active human calcium channel $\alpha 1G$ -c may have several different physical forms. Human calcium channel $\alpha 1G$ -c may exist as a full-length nascent or unprocessed polypeptide, or as partially processed polypeptides or combinations of processed polypeptides. The full-length nascent human calcium channel $\alpha 1G$ -c polypeptide may be posttranslationally modified by specific proteolytic cleavage events, which result in the formation of fragments of the full-length nascent polypeptide. A fragment, or physical association of fragments may have the full biological activity associated with human calcium channel $\alpha 1G$ -c, however, the degree of human calcium channel $\alpha 1G$ -c activity may vary between individual human calcium channel $\alpha 1G$ -c fragments and physically associated human calcium channel $\alpha 1G$ -c polypeptide fragments.

The cloned human calcium channel $\alpha 1G$ -c DNA obtained through the methods described herein may be recombinantly expressed by molecular cloning into an expression vector containing a suitable promoter and other appropriate transcription regulatory elements, and transferred into prokaryotic or eukaryotic host cells to produce recombinant human calcium channel $\alpha 1G$ -c protein. Techniques for such manipulations are fully described in Maniatis, T. et al., *supra*, and are well known in the art.

Expression vectors are defined herein as DNA sequences that are required for the transcription of cloned copies of genes and the translation of their mRNAs in an appropriate host. Such vectors can be used to express eukaryotic genes in a variety of hosts such as bacteria including *E. coli*, blue-green algae, plant cells, insect cells, fungal cells including yeast cells, and animal cells.

Specifically designed vectors allow the shuttling of DNA between hosts such as bacteria-yeast or bacteria-animal cells or bacteria-fungal cells or bacteria-invertebrate cells. An appropriately constructed expression vector should contain: an origin of replication for autonomous replication in host cells, selectable markers, a limited number of useful restriction enzyme sites, a potential for high copy number, and active promoters. A promoter is defined as a DNA sequence that directs RNA polymerase to bind to DNA and initiate RNA synthesis. A strong promoter is one that causes mRNAs to be initiated at high frequency. Expression vectors may include, but are not limited to, cloning vectors, modified cloning vectors, specifically designed plasmids or viruses.

A variety of mammalian expression vectors may be used to express recombinant human calcium channel $\alpha 1G$ -c in mammalian cells. Commercially available mammalian expression vectors which may be suitable for recombinant human calcium channel $\alpha 1G$ -c expression, include but are not limited to, pMAMneo (Clontech), pcDNA3 (Invitrogen), pMC1neo (Stratagene), pXT1 (Stratagene), pSG5 (Stratagene), EBO-pSV2-neo (ATCC 37593) pBPV-1(8-2) (ATCC 37110), pdBPV-MMTneo(342-12) (ATCC 37224), pRSVgpt (ATCC 37199), pRSVneo (ATCC 37198), pSV2-dhfr (ATCC 37146), pUCTag (ATCC 37460), and IZD35 (ATCC 37565).

A variety of bacterial expression vectors may be used to express recombinant human calcium channel $\alpha 1G$ -c in bacterial cells. Commercially available bacterial expression vectors which may be suitable for recombinant human calcium channel $\alpha 1G$ -c expression include, but are not limited to pET vectors (Novagen) and pQE vectors (Qiagen).

A variety of fungal cell expression vectors may be used to express recombinant human calcium channel $\alpha 1G$ -c in fungal cells such as yeast. Commercially available fungal cell expression vectors which may be suitable for recombinant human calcium channel $\alpha 1G$ -c expression include but are not limited to pYES2 (Invitrogen) and Pichia expression vector (Invitrogen).

A variety of insect cell expression vectors may be used to express recombinant human calcium channel $\alpha 1G$ -c in insect cells. Commercially available insect cell expression vectors that may be suitable for recombinant expression of human calcium channel $\alpha 1G$ -c include but are not limited to pBlueBacII (Invitrogen).

DNA encoding human calcium channel $\alpha 1G$ -c may be cloned into an expression vector for expression in a recombinant host cell. Recombinant host cells may be prokaryotic or eukaryotic, including but not limited to bacteria such as

E. coli. fungal cells such as yeast, mammalian cells including but not limited to cell lines of human, bovine, porcine, monkey and rodent origin, and insect cells including but not limited to drosophila and silkworm derived cell lines. Cell lines derived from mammalian species which may be suitable and which are commercially available, include but are not limited to, CV-1 (ATCC CCL 70), COS-1 (ATCC CRL 1650), COS-7 (ATCC CRL 1651), CHO-K1 (ATCC CCL 61), 3T3 (ATCC CCL 92), NIH/3T3 (ATCC CRL 1658), HeLa (ATCC CCL 2), C1271 (ATCC CRL 1616), BS-C-1 (ATCC CCL 26), MRC-5 (ATCC CCL 171), L-cells, and HEK-293 (ATCC CRL1573).

The expression vector may be introduced into host cells via any one of a number of techniques including but not limited to transformation, transfection, protoplast fusion, lipofection, and electroporation. The expression vector-containing cells are clonally propagated and individually analyzed to determine whether they produce human calcium channel $\alpha 1G$ -c protein. Identification of human calcium channel $\alpha 1G$ -c expressing host cell clones may be done by several means, including but not limited to immunological reactivity with anti-human calcium channel $\alpha 1G$ -c antibodies, and the presence of host cell-associated human calcium channel $\alpha 1G$ -c activity.

Expression of human calcium channel $\alpha 1G$ -c DNA may also be performed using in vitro produced synthetic mRNA. Synthetic mRNA or mRNA isolated from human calcium channel $\alpha 1G$ -c producing cells can be efficiently translated in various cell-free systems, including but not limited to wheat germ extracts and reticulocyte extracts, as well as efficiently translated in cell based systems, including but not limited to microinjection into frog oocytes, with microinjection into frog oocytes being generally preferred.

To determine the human calcium channel $\alpha 1G$ -c DNA sequence(s) that yields optimal levels of human calcium channel $\alpha 1G$ -c activity and/or human calcium channel $\alpha 1G$ -c protein, human calcium channel $\alpha 1G$ -c DNA molecules including, but not limited to, the following can be constructed: the full-length open reading frame of the human calcium channel $\alpha 1G$ -c cDNA encoding the approximately 252 kDa protein from approximately base 1 to approximately base 6822 (these numbers correspond to first nucleotide of first methionine and last nucleotide before the first stop codon) and several constructs containing portions of the cDNA encoding human calcium channel $\alpha 1G$ -c protein. All constructs can be designed to contain none, all or portions of the 5' or the 3' untranslated region of human calcium channel $\alpha 1G$ -c cDNA. Human calcium channel $\alpha 1G$ -c activity and levels of protein expression can be determined following the introduction, both singly and in combination, of these constructs into appropriate host cells. Following determination of the human calcium channel $\alpha 1G$ -c DNA cassette yielding optimal expression in transient assays, this human calcium channel $\alpha 1G$ -c DNA construct is transferred to a variety of expression vectors, for expression in host cells including, but not limited to, mammalian cells, baculovirus-infected insect cells, *E. coli* and the yeast *S. cerevisiae*.

Host cell transfectants and microinjected oocytes may be used to assay both the levels of human calcium channel $\alpha 1G$ -c channel activity and levels of human calcium channel $\alpha 1G$ -c protein by the following methods. In the case of recombinant host cells, this involves the co-transfection of one or possibly two or more plasmids, containing the human calcium channel $\alpha 1G$ -c DNA encoding one or more fragments or subunits. In the case of oocytes, this involves the co-injection of synthetic RNAs for

human calcium channel $\alpha 1G$ -c protein. Following an appropriate period of time to allow for expression, cellular protein is metabolically labelled with, for example ^{35}S -methionine for 24 hours, after which cell lysates and cell culture supernatants are harvested and subjected to immunoprecipitation with polyclonal antibodies directed against the human calcium channel $\alpha 1G$ -c protein.

Other methods for detecting human calcium channel $\alpha 1G$ -c activity involve the direct measurement of human calcium channel $\alpha 1G$ -c activity in whole cells transfected with human calcium channel $\alpha 1G$ -c cDNA or oocytes injected with human calcium channel $\alpha 1G$ -c mRNA. Human calcium channel $\alpha 1G$ -c activity is measured by biological characteristics of the host cells expressing human calcium channel $\alpha 1G$ -c DNA. In the case of recombinant host cells expressing human calcium channel $\alpha 1G$ -c patch voltage clamp techniques can be used to measure receptor activity and quantitate human calcium channel $\alpha 1G$ -c protein. In the case of oocytes patch clamp as well as two-electrode voltage clamp techniques can be used to measure calcium channel $\alpha 1G$ -c activity and quantitate human calcium channel $\alpha 1G$ -c protein by determining single channel and whole cell conductances.

Levels of human calcium channel $\alpha 1G$ -c protein in host cells are quantitated by immunoaffinity and/or ligand affinity techniques. Cells expressing human calcium channel $\alpha 1G$ -c can be assayed for the number of human calcium channel $\alpha 1G$ -c molecules expressed by measuring the amount of radioactive ligand binding to cell membranes. Human calcium channel $\alpha 1G$ -c-specific affinity beads or human calcium channel $\alpha 1G$ -c-specific antibodies are used to isolate for example ^{35}S -methionine labelled or unlabelled human calcium channel $\alpha 1G$ -c protein. Labelled human calcium channel $\alpha 1G$ -c protein is analyzed by SDS-PAGE. Unlabelled human calcium channel $\alpha 1G$ -c protein is detected by Western blotting, ELISA or RIA assays employing human calcium channel $\alpha 1G$ -c specific antibodies.

Because the genetic code is degenerate, more than one codon may be used to encode a particular amino acid, and therefore, the amino acid sequence can be encoded by any of a set of similar DNA oligonucleotides. Only one member of the set will be identical to the human calcium channel $\alpha 1G$ -c sequence but will be capable of hybridizing to human calcium channel $\alpha 1G$ -c DNA even in the presence of DNA oligonucleotides with mismatches under appropriate conditions. Under alternate conditions, the mismatched DNA oligonucleotides may still hybridize to the human calcium channel $\alpha 1G$ -c DNA to permit identification and isolation of human calcium channel $\alpha 1G$ -c encoding DNA.

DNA encoding human calcium channel $\alpha 1G$ -c from a particular organism may be used to isolate and purify homologues of human calcium channel $\alpha 1G$ -c from other organisms. To accomplish this, the first human calcium channel $\alpha 1G$ -c DNA may be mixed with a sample containing DNA encoding homologues of human calcium channel $\alpha 1G$ -c under appropriate hybridization conditions. The hybridized DNA complex may be isolated and the DNA encoding the homologous DNA may be purified therefrom.

It is known that there is a substantial amount of redundancy in the various codons that code for specific amino acids. Therefore, this invention is also directed to those DNA sequences that contain alternative codons that code for the eventual translation of the identical amino acid. For pur-

poses of this specification, a sequence bearing one or more replaced codons will be defined as a degenerate variation. Also included within the scope of this invention are mutations either in the DNA sequence or the translated protein which do not substantially alter the ultimate physical properties of the expressed protein. For example, substitution of valine for leucine, arginine for lysine, or asparagine for glutamine may not cause a change in functionality of the polypeptide. Such substitutions are well known and are described, for instance in *Molecular Biology of the Gene*, 4th Ed. Benjamin Cummings Pub. Co. by Watson et al.

It is known that DNA sequences coding for a peptide may be altered so as to code for a peptide having properties that are different than those of the naturally occurring peptide. Methods of altering the DNA sequences include, but are not limited to site directed mutagenesis. Examples of altered properties include but are not limited to changes in the affinity of an enzyme for a substrate or a receptor for a ligand.

As used herein, a "functional derivative" of human calcium channel $\alpha 1G-c$ is a compound that possesses a biological activity (either functional or structural) that is substantially similar to the biological activity of human calcium channel $\alpha 1G-c$. The term "functional derivatives" is intended to include the "fragments," "variants," "degenerate variants," "analogs" and "homologues" or to "chemical derivatives" of human calcium channel $\alpha 1G-c$. The term "fragment" is meant to refer to any polypeptide subset of human calcium channel $\alpha 1G-c$. The term "variant" is meant to refer to a molecule substantially similar in structure and function to either the entire human calcium channel $\alpha 1G-c$ molecule or to a fragment thereof. A molecule is "substantially similar" to human calcium channel $\alpha 1G-c$ if both molecules have substantially similar structures or if both molecules possess similar biological activity. Therefore, if the two molecules possess substantially similar activity, they are considered to be variants even if the structure of one of the molecules is not found in the other or even if the two amino acid sequences are not identical. The term "analog" refers to a molecule substantially similar in function to either the entire human calcium channel $\alpha 1G-c$ molecule or to a fragment thereof. The term "functional" with respect to a calcium channel activity means that the channel is able to provide for and regulate entry of calcium channel selective ions, including, but not limited to Ca^{+2} or Ba^{+2} or ions that block the flow of Ca^{+2} or Ba^{+2} , in response to a stimulus and/or bind ligands with affinity for the channel. Preferably such channel activity is distinguishable, such as by electrophysiological, pharmacological and other means known to those of skill in the art, from any endogenous calcium channel activity that is in the host cell.

Following expression of human calcium channel $\alpha 1G-c$ in a recombinant host cell, human calcium channel $\alpha 1G-c$ protein may be recovered to provide human calcium channel $\alpha 1G-c$ in active form. Several human calcium channel $\alpha 1G-c$ purification procedures are available and suitable for use. As described above for purification of human calcium channel $\alpha 1G-c$ from natural sources, recombinant human calcium channel $\alpha 1G-c$ may be purified from cell lysates and extracts, or from conditioned culture medium, by various combinations of, or individual application of salt fractionation, ion exchange chromatography, size exclusion chromatography, hydroxylapatite adsorption chromatography and hydrophobic interaction chromatography.

In addition, recombinant human calcium channel $\alpha 1G-c$ can be separated from other cellular proteins by

use of an immunoaffinity column made with monoclonal or polyclonal antibodies specific for full length nascent human calcium channel $\alpha 1G-c$, polypeptide fragments of human calcium channel $\alpha 1G-c$ or human calcium channel $\alpha 1G-c$ subunits.

Monospecific antibodies to human calcium channel $\alpha 1G-c$ are purified from mammalian antisera containing antibodies reactive against human calcium channel $\alpha 1G-c$ or are prepared as monoclonal antibodies reactive with human calcium channel $\alpha 1G-c$ using the technique of Kohler and Milstein, *Nature* 256: 495-497 (1975). Monospecific antibody as used herein is defined as a single antibody species or multiple antibody species with homogeneous binding characteristics for human calcium channel $\alpha 1G-c$. Homogeneous binding as used herein refers to the ability of the antibody species to bind to a specific antigen or epitope, such as those associated with the human calcium channel $\alpha 1G-c$, as described above. Human calcium channel $\alpha 1G-c$ specific antibodies are raised by immunizing animals such as mice, rats, guinea pigs, rabbits, goats, horses and the like, with rabbits being preferred, with an appropriate concentration of human calcium channel $\alpha 1G-c$ either with or without an immune adjuvant.

Preimmune serum is collected prior to the first immunization. Each animal receives between about 0.1 mg and about 1000 mg of human calcium channel $\alpha 1G-c$ associated with an acceptable immune adjuvant. Such acceptable adjuvants include, but are not limited to, Freund's complete, Freund's incomplete, alum-precipitate, water in oil emulsion containing *Corynebacterium parvum* and tRNA. The initial immunization consists of human calcium channel $\alpha 1G-c$ in, preferably, Freund's complete adjuvant at multiple sites either subcutaneously (SC), intraperitoneally (IP) or both. Each animal is bled at regular intervals, preferably weekly, to determine antibody titer. The animals may or may not receive booster injections following the initial immunization. Those animals receiving booster injections are generally given an equal amount of the antigen in Freund's incomplete adjuvant by the same route. Booster injections are given at about three-week intervals until maximal titers are obtained. At about 7 days after each booster immunization or about weekly after a single immunization, the animals are bled, the serum collected, and aliquots are stored at about $-20^{\circ}C$.

Monoclonal antibodies (mAb) reactive with human calcium channel $\alpha 1G-c$ are prepared by immunizing inbred mice, preferably Balb/c, with human calcium channel $\alpha 1G-c$. The mice are immunized by the IP or SC route with about 0.1 mg to about 10 mg, preferably about 1 mg, of human calcium channel $\alpha 1G-c$ in about 0.5 ml buffer or saline incorporated in an equal volume of an acceptable adjuvant, as discussed above. Freund's complete adjuvant is preferred. The mice receive an initial immunization on day 0 and are rested for about 3 to about 30 weeks. Immunized mice are given one or more booster immunizations of about 0.1 to about 10 mg of human calcium channel $\alpha 1G-c$ in a buffer solution such as phosphate buffered saline by the intravenous (IV) route. Lymphocytes, from antibody positive mice, preferably splenic lymphocytes, are obtained by removing spleens from immunized mice by standard procedures known in the art. Hybridoma cells are produced by mixing the splenic lymphocytes with an appropriate fusion partner, preferably myeloma cells, under conditions that will allow the formation of stable hybridomas. Fusion partners may include, but are not limited to: mouse myelomas P3/NS1/Ag4-1; MPC-11; S-194 and Sp 2/0, with Sp 2/0 being generally preferred. The antibody producing cells and

myeloma cells are fused in polyethylene glycol, about 1000 mol. wt., at concentrations from about 30% to about 50%. Fused hybridoma cells are selected by growth in hypoxanthine, thymidine and aminopterin supplemented Dulbecco's Modified Eagles Medium (DMEM) by procedures known in the art. Supernatant fluids are collected from growth positive wells on about days 14, 18, and 21 and are screened for antibody production by an immunoassay such as solid phase immunoradioassay (SPIRA) using human calcium channel $\alpha 1G$ -c as the antigen. The culture fluids are also tested in the Ouchterlony precipitation assay to determine the isotype of the mAb. Hybridoma cells from antibody positive wells are cloned by a technique such as the soft agar technique of MacPherson, *Soft Agar Techniques*, in *Tissue Culture Methods and Applications*, Kruse and Paterson, Eds., Academic Press, 1973.

Monoclonal antibodies are produced *in vivo* by injection of pristane primed Balb/c mice, approximately 0.5 ml per mouse, with about 2×10^6 to about 6×10^6 hybridoma cells about 4 days after priming. Ascites fluid is collected at approximately 8–12 days after cell transfer and the monoclonal antibodies are purified by techniques known in the art.

In vitro production of anti-human calcium channel $\alpha 1G$ -c mAb is carried out by growing the hybridoma in DMEM containing about 2% fetal calf serum to obtain sufficient quantities of the specific mAb. The mAb are purified by techniques known in the art.

Antibody titers of ascites or hybridoma culture fluids are determined by various serological or immunological assays which include, but are not limited to, precipitation, passive agglutination, enzyme-linked immunosorbent antibody (ELISA) technique and radioimmunoassay (RIA) techniques. Similar assays are used to detect the presence of human calcium channel $\alpha 1G$ -c in body fluids or tissue and cell extracts.

It is readily apparent to those skilled in the art that the above described methods for producing monospecific antibodies may be utilized to produce antibodies specific for human calcium channel $\alpha 1G$ -c polypeptide fragments, or full-length nascent human calcium channel $\alpha 1G$ -c polypeptide, or the individual human calcium channel $\alpha 1G$ -c domains. Specifically, it is readily apparent to those skilled in the art that monospecific antibodies may be generated which are specific for human calcium channel $\alpha 1G$ -c by immunizing an animal with an antigenic peptide derived from the 23 amino acid insert, or fragments thereof.

Human calcium channel $\alpha 1G$ -c antibody affinity columns are made by adding the antibodies to Affigel-10 (Bio-Rad), a gel support which is activated with N-hydroxysuccinimide esters such that the antibodies form covalent linkages with the agarose gel bead support. The antibodies are then coupled to the gel via amide bonds with the spacer arm. The remaining activated esters are then quenched with 1M ethanolamine HCl (pH 8). The column is washed with water followed by 0.23 M glycine HCl (pH 2.6) to remove any non-conjugated antibody or extraneous protein. The column is then equilibrated in phosphate buffered saline (pH 7.3) and the cell culture supernatants or cell extracts containing human calcium channel $\alpha 1G$ -c or human calcium channel $\alpha 1G$ -c subunits are slowly passed through the column. The column is then washed with phosphate buffered saline until the optical density (A_{280}) falls to background, then the protein is eluted with 0.23 M glycine-HCl (pH 2.6). The purified human calcium channel $\alpha 1G$ -c protein is then dialyzed against phosphate buffered saline.

DNA clones, termed human calcium channel $\alpha 1G$ -c, are identified which encode proteins that, when expressed in a recombinant host cell, form channels that regulate calcium influx and are sensitive to NPPB (5-Nitro-2-(3-phenylpropylamino)benzoic acid). The expression of human calcium channel $\alpha 1G$ -c DNA results in the reconstitution of the properties observed in oocytes injected with human calcium channel $\alpha 1G$ -c-encoding poly (A)⁺ RNA, including direct activation with the appropriate stimuli.

The present invention is also directed to methods for screening for compounds that modulate the expression of DNA or RNA encoding human calcium channel $\alpha 1G$ -c as well as the quantity of expressed human calcium channel $\alpha 1G$ -c protein. The term "compound" refers to small organic or inorganic molecules (including divalent ions), synthetic or natural amino acid polypeptides, proteins, or synthetic or natural nucleic acid sequences. Compounds may modulate by increasing or attenuating the expression of DNA or RNA encoding human calcium channel $\alpha 1G$ -c, or the quantity of cell surface human calcium channel $\alpha 1G$ -c protein. Compounds that modulate the expression of DNA or RNA encoding human calcium channel $\alpha 1G$ -c or the quantity of human calcium channel $\alpha 1G$ -c protein may be detected by a variety of assays. Assays to measure changes in the level of expression of $\alpha 1G$ -c can be accomplished by various means, well known in the art, for example changes in the quantity of mRNA, intracellular protein (newly synthesized protein being processed within the endoplasmic reticulum or Golgi apparatus), or cell surface protein. Levels of mRNA are detected by reverse transcription polymerase chain reaction (RT-PCR) or by differential gene expression (quantitative gene chips). Immunoaffinity quantitates levels of protein both within and on the surface of host cells. Protein-specific affinity beads or specific antibodies are used to isolate for example ³⁵S-methionine labelled or unlabelled protein. Labelled protein is analyzed by SDS-PAGE. Unlabelled protein is detected by Western blotting, cell surface detection by fluorescent cell sorting, ELISA or RIA employing specific antibodies.

Assays that use eukaryotic cells for identifying compounds that modulate human $\alpha 1G$ -c calcium channel activity are also provided. In practicing these assays the eukaryotic cell that expresses the heterologous human $\alpha 1G$ -c calcium channel encoded by a DNA sequence described herein, is in a solution containing a test compound and a calcium channel selective ion, the cell membrane is depolarized, and current flowing into the cell is detected. If the test compound is one that modulates calcium channel activity, the current that is detected is different from that produced by depolarizing the same or a substantially identical cell in the presence of the same calcium channel-selective ion but in the absence of the compound. In preferred embodiments, the cells are mammalian cells, most preferably HEK293 cells, or amphibian oocytes. The assay method comprises the steps of: (a) measuring the activity of the human $\alpha 1G$ -c in a cell that expresses the human $\alpha 1G$ -c calcium channel; (b) contacting a compound with the cell; and (c) monitoring changes in the cell. In these assays, an agonist would increase Ca influx with no elevated K depolarizing stimulus, in the presence of concentrations of K that normally are not enough to activate the channels or shift the voltage dependence of inactivation. In these assays, an antagonist would block Ca influx induced by elevated potassium. Assays that measure electrophysiological calcium channel function measure the amount or duration of Ca

influx, for example by using Ca sensitive dyes such as Fluo-3 or radioactive ions such as ^{45}Ca or voltage clamp techniques. Voltage sensitive dyes and current clamp electrophysiological techniques can be used to measure depolarizations resulting from Ca influx. Yet another embodiment of the test method measures "downstream" effects of Ca influx by using a transcription based assay under inducible control of a Ca sensitive promotor, as described in PCT International Patent Application No. PCT/US91/5625, filed Aug. 7, 1991.

These assays may be a simple "yes/no" assays to determine whether there is a change in expression or function or they may be made quantitative by comparing the expression or function of a test sample with the levels of expression or function in a standard sample. Modulators identified any of these processes are useful as therapeutic agents.

Modulators identified in the assays disclosed herein are useful candidates as therapeutic agents for the treatment disorders that are mediated by human $\alpha 1\text{G-c}$ activity. Such activities that may be mediated by human $\alpha 1\text{G-c}$ include, epilepsy, schizophrenia, depression, sleep disorders, stress, endocrine disorders, respiratory disorder, peripheral muscle disorders, muscle excitability, Cushing's disease, fertilization, contraception, disorders involving neuronal firing regulation, respiratory disorders, hypertension, cardiac rhythm, potentiation of synaptic signals, improving arterial compliance in systolic hypertension, vascular tone such as by decreasing vascular swelling, cardiac hypertrophy, cardiac fibrosis, atherosclerosis, cardiovascular disorders, including but not limited to: myocardial infarct, cardiac arrhythmia, heart failure and angina pectoris, and cellular growth (protein synthesis, cell differentiation, and proliferation). The compounds that modulate human $\alpha 1\text{G-c}$ calcium channel activity may be useful in regulating vascular smooth muscle tone, either vasodilating or vasoconstricting in: (a) treatments for reestablishing blood pressure control, e.g., following traumatic injury, surgery or cardiopulmonary bypass, and in prophylactic treatments designed to minimize cardiovascular effects of anaesthetic drugs; (b) treatments for improving vascular reflexes and blood pressure control by the autonomic nervous system. The compounds that modulate human $\alpha 1\text{G-c}$ calcium channel activity may also be useful in treatments of urological disorders and reproductive disorders: (a) treating and restoring renal function following surgery, traumatic injury, uremia and adverse drug reactions; (b) treating bladder dysfunctions; and (c) uremic neuronal toxicity and hypotension in patients on hemodialysis; reproductive disorders; (d) disorders of sexual function including impotence; (e) alcoholic impotence (under autonomic control that may be subject to T-type calcium channel controls); and (f) fertility (via direct action upon Sertoli cells (in males) or the zona pellucida (for mammalian eggs) or by modulation of hormonal feedback). The compounds that modulate human $\alpha 1\text{G-c}$ calcium channel activity may be useful in treatments of hepatic disorders in treating and reducing neuronal toxicity and autonomic nervous system damage resulting from acute overconsumption of alcohol. The compounds that modulate human $\alpha 1\text{G-c}$ calcium channel activity may be useful treatments for neurologic disorders; (a) epilepsy and diencephalic epilepsy; (b) Parkinson's disease; and (c) aberrant temperature control, such as, abnormalities of shivering and sweat gland secretion and peripheral vascular blood supply. The compounds that modulate human $\alpha 1\text{G-c}$ calcium channel activity may be useful for treating abnormal respiration, e.g., post-surgical complications of anesthetics

and endocrine disorders; (a) aberrant pituitary and hypothalamic functions including abnormal secretion of noradrenaline, dopamine and other hormones; and (b) treatments for overproduction of insulin, thyroxine adrenaline and other hormonal imbalances.

Kits containing human calcium channel $\alpha 1\text{G-c}$ DNA or RNA, antibodies to human calcium channel $\alpha 1\text{G-c}$, or human calcium channel $\alpha 1\text{G-c}$ protein may be prepared. Such kits are used to detect DNA that hybridizes to human calcium channel $\alpha 1\text{G-c}$ DNA or to detect the presence of human calcium channel $\alpha 1\text{G-c}$ protein or peptide fragments in a sample. Such characterization is useful for a variety of purposes including but not limited to forensic analyses, diagnostic applications, and epidemiological studies.

The DNA molecules, RNA molecules, recombinant protein and antibodies of the present invention may be used to screen and measure levels of human calcium channel $\alpha 1\text{G-c}$ DNA, human calcium channel $\alpha 1\text{G-c}$ RNA or human calcium channel $\alpha 1\text{G-c}$ protein. The recombinant proteins, DNA molecules, RNA molecules and antibodies lead themselves to the formulation of kits suitable for the detection and typing of human calcium channel $\alpha 1\text{G-c}$. Such a kit would comprise a compartmentalized carrier suitable to hold in close confinement at least one container. The carrier would further comprise reagents such as recombinant human calcium channel $\alpha 1\text{G-c}$ protein or anti-human calcium channel $\alpha 1\text{G-c}$ antibodies suitable for detecting human calcium channel $\alpha 1\text{G-c}$. The carrier may also contain a means for detection such as labeled antigen or enzyme substrates or the like.

Nucleotide sequences that are complementary to the human calcium channel $\alpha 1\text{G-c}$ encoding DNA sequence can be synthesized for antisense therapy. These antisense molecules may be DNA, stable derivatives of DNA such as phosphorothioates or methylphosphonates, RNA, stable derivatives of RNA such as 2'-O-alkylRNA, or other human calcium channel $\alpha 1\text{G-c}$ antisense oligonucleotide mimetics. Human calcium channel $\alpha 1\text{G-c}$ antisense molecules may be introduced into cells by microinjection, liposome encapsulation or by expression from vectors harboring the antisense sequence. Human calcium channel $\alpha 1\text{G-c}$ antisense therapy may be particularly useful for the treatment of diseases where it is beneficial to reduce human calcium channel $\alpha 1\text{G-c}$ activity.

Human calcium channel $\alpha 1\text{G-c}$ gene therapy may be used to introduce human calcium channel $\alpha 1\text{G-c}$ into the cells of target organisms. The human calcium channel $\alpha 1\text{G-c}$ gene can be ligated into viral vectors that mediate transfer of the human calcium channel $\alpha 1\text{G-c}$ DNA by infection of recipient host cells. Suitable viral vectors include retrovirus, adenovirus, adeno-associated virus, herpes virus, vaccinia virus, polio virus and the like. Alternatively, human calcium channel $\alpha 1\text{G-c}$ DNA can be transferred into cells for gene therapy by non-viral techniques including receptor-mediated targeted DNA transfer using ligand-DNA conjugates or adenovirus-ligand-DNA conjugates, lipofection membrane fusion or direct microinjection. These procedures and variations thereof are suitable for ex vivo as well as in vivo human calcium channel $\alpha 1\text{G-c}$ gene therapy. Human calcium channel $\alpha 1\text{G-c}$ gene therapy may be particularly useful for the treatment of diseases where it is beneficial to elevate human calcium channel $\alpha 1\text{G-c}$ activity.

Pharmaceutically useful compositions comprising human calcium channel $\alpha 1\text{G-c}$ DNA, human calcium channel

alpha1G-c RNA, or human calcium channel alpha1G-c protein, or modulators of human calcium channel alpha1G-c activity, may be formulated according to known methods such as by the admixture of a pharmaceutically acceptable carrier. Examples of such carriers and methods of formulation may be found in Remington's Pharmaceutical Sciences. To form a pharmaceutically acceptable composition suitable for effective administration, such compositions will contain an effective amount of the protein, DNA, RNA, or modulator.

Therapeutic or diagnostic compositions of the invention are administered to an individual in amounts sufficient to treat or diagnose disorders in which modulation of human calcium channel alpha1G-c-related activity is indicated. The effective amount may vary according to a variety of factors such as the individual's condition, weight, sex and age. Other factors include the mode of administration. The pharmaceutical compositions may be provided to the individual by a variety of routes such as subcutaneous, topical, oral and intramuscular.

The term "chemical derivative" describes a molecule that contains additional chemical moieties that are not normally a part of the base molecule. Such moieties may improve the solubility, half-life, absorption, etc. of the base molecule. Alternatively the moieties may attenuate undesirable side effects of the base molecule or decrease the toxicity of the base molecule. Examples of such moieties are described in a variety of texts, such as Remington's Pharmaceutical Sciences.

Compounds identified according to the methods disclosed herein may be used alone at appropriate dosages defined by routine testing in order to obtain optimal inhibition of the human calcium channel alpha1G-c or its activity while minimizing any potential toxicity. In addition, co-administration or sequential administration of other agents may be desirable.

The present invention also has the objective of providing suitable topical, oral, systemic and parenteral pharmaceutical formulations for use in the novel methods of treatment of the present invention. The compositions containing compounds or modulators identified according to this invention as the active ingredient for use in the modulation of human calcium channel alpha1G-c receptors can be administered in a wide variety of therapeutic dosage forms in conventional vehicles for administration. For example, the compounds or modulators can be administered in such oral dosage forms as tablets, capsules (each including timed release and sustained release formulations), pills, powders, granules, elixirs, tinctures, solutions, suspensions, syrups and emulsions, or by injection. Likewise, they may also be administered in intravenous (both bolus and infusion), intraperitoneal, subcutaneous, topical with or without occlusion, or intramuscular form, all using forms well known to those of ordinary skill in the pharmaceutical arts. An effective but non-toxic amount of the compound desired can be employed as a human calcium channel alpha1G-c modulating agent.

The daily dosage of the products may be varied over a wide range from 0.01 to 1,000 mg per patient, per day. For oral administration, the compositions are preferably provided in the form of scored or unscored tablets containing 0.01, 0.05, 0.1, 0.5, 1.0, 2.5, 5.0, 10.0, 15.0, 25.0, and 50.0 milligrams of the active ingredient for the symptomatic adjustment of the dosage to the patient to be treated. An effective amount of the drug is ordinarily supplied at a dosage level of from about 0.0001 mg/kg to about 100 mg/kg of body weight per day. The range is more particu-

larly from about 0.001 mg/kg to 10 mg/kg of body weight per day. The dosages of the human calcium channel alpha1G-c modulators are adjusted when combined to achieve desired effects. On the other hand, dosages of these various agents may be independently optimized and combined to achieve a synergistic result wherein the pathology is reduced more than it would be if either agent were used alone.

Advantageously, compounds or modulators of the present invention may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three or four times daily. Furthermore, compounds or modulators for the present invention can be administered in intranasal form via topical use of suitable intranasal vehicles, or via transdermal routes, using those forms of transdermal skin patches well known to those of ordinary skill in that art. To be administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen.

For combination treatment with more than one active agent, where the active agents are in separate dosage formulations, the active agents can be administered concurrently, or they each can be administered at separately staggered times.

The dosage regimen utilizing the compounds or modulators of the present invention is selected in accordance with a variety of factors including type, species, age, weight, sex and medical condition of the patient; the severity of the condition to be treated; the route of administration; the renal and hepatic function of the patient; and the particular compound thereof employed. A physician or veterinarian of ordinary skill can readily determine and prescribe the effective amount of the drug required to prevent, counter or arrest the progress of the condition. Optimal precision in achieving concentrations of drug within the range that yields efficacy without toxicity requires a regimen based on the kinetics of the drug's availability to target sites. This involves a consideration of the distribution, equilibrium, and elimination of a drug.

In the methods of the present invention, the compounds or modulators herein described in detail can form the active ingredient, and are typically administered in admixture with suitable pharmaceutical diluents, excipients or carriers (collectively referred to herein as "carrier" materials) suitably selected with respect to the intended form of administration, that is, oral tablets, capsules, elixirs, syrups and the like, and consistent with conventional pharmaceutical practices.

For instance, for oral administration in the form of a tablet or capsule, the active drug component can be combined with an oral, non-toxic pharmaceutically acceptable inert carrier such as ethanol, glycerol, water and the like. Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents and coloring agents can also be incorporated into the mixture. Suitable binders include, without limitation, starch, gelatin, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes and the like. Lubricants used in these dosage forms include, without limitation, sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride and the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum and the like.

For liquid forms the active drug component can be combined in suitably flavored suspending or dispersing agents such as the synthetic and natural gums, for example, tragacanth, acacia, methyl-cellulose and the like. Other dispersing agents that may be employed include glycerin and the like. For parenteral administration, sterile suspensions and solutions are desired. Isotonic preparations, which generally contain suitable preservatives, are employed when intravenous administration is desired.

Topical preparations containing the active drug component can be admixed with a variety of carrier materials well known in the art, such as, eg., alcohols, aloe vera gel, allantoin, glycerine, vitamin A and E oils, mineral oil, PPG2 myristyl propionate, and the like, to form, eg., alcoholic solutions, topical cleansers, cleansing creams, skin gels, skin lotions, and shampoos in cream or gel formulations.

The compounds or modulators of the present invention can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine or phosphatidylcholines.

Compounds of the present invention may also be delivered by the use of monoclonal antibodies as individual carriers to which the compound molecules are coupled. The compounds or modulators of the present invention may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinyl-pyrrolidone, pyran copolymer, polyhydroxypropylmethacryl-amidephenol, polyhydroxy-ethylaspartamidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues. Furthermore, the compounds or modulators of the present invention may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polyepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydro-pyrans, polycyanoacrylates and cross-linked or amphipathic block copolymers of hydrogels.

For oral administration, the compounds or modulators may be administered in capsule, tablet, or bolus form or alternatively they can be mixed in the animals feed. The capsules, tablets, and boluses are comprised of the active ingredient in combination with an appropriate carrier vehicle such as starch, talc, magnesium stearate, or di-calcium phosphate. These unit dosage forms are prepared by intimately mixing the active ingredient with suitable finely-powdered inert ingredients including diluents, fillers, disintegrating agents, and/or binders such that a uniform mixture is obtained. An inert ingredient is one that will not react with the compounds or modulators and which is non-toxic to the animal being treated. Suitable inert ingredients include starch, lactose, talc, magnesium stearate, vegetable gums and oils, and the like. These formulations may contain a widely variable amount of the active and inactive ingredients depending on numerous factors such as the size and type of the animal species to be treated and the type and severity of the infection. The active ingredient may also be administered as an additive to the feed by simply mixing the compound with the feedstuff or by applying the compound to the surface of the feed. Alternatively the active ingredient may be mixed with an inert carrier and the resulting composition may then either be mixed with the feed or fed directly to the animal. Suitable inert carriers include corn meal, citrus meal, fermentation residues, soya grits, dried grains and the like. The active ingredients are intimately mixed with these inert carriers by grinding, stirring, milling, or tumbling such that the final composition contains from 0.001 to 5% by weight of the active ingredient.

The compounds or modulators may alternatively be administered parenterally via injection of a formulation consisting of the active ingredient dissolved in an inert liquid carrier. Injection may be either intramuscular, intraluminal, intratracheal, or subcutaneous. The injectable formulation consists of the active ingredient mixed with an appropriate inert liquid carrier. Acceptable liquid carriers include the vegetable oils such as peanut oil, cotton seed oil, sesame oil and the like as well as organic solvents such as solketal, glycerol formal and the like. As an alternative, aqueous parenteral formulations may also be used. The vegetable oils are the preferred liquid carriers. The formulations are prepared by dissolving or suspending the active ingredient in the liquid carrier such that the final formulation contains from 0.005 to 10% by weight of the active ingredient.

Topical application of the compounds or modulators is possible through the use of a liquid drench or a shampoo containing the instant compounds or modulators as an aqueous solution or suspension. These formulations generally contain a suspending agent such as bentonite and normally will also contain an antifoaming agent. Formulations containing from 0.005 to 10% by weight of the active ingredient are acceptable. Preferred formulations are those containing from 0.01 to 5% by weight of the instant compounds or modulators.

The following examples illustrate the present invention without, however, limiting the same thereto.

EXAMPLE 1

Generation of a Human Thalamus Library cDNA Synthesis First Strand Synthesis

Approximately 5 μ g of human thalamus mRNA (Clontech) was used to synthesize cDNA using the cDNA synthesis kit (Life Technologies). Two microliters of Not1 primer adapter was added to 5 μ l of mRNA and the mixture was heated to 70° C. for 10 minutes and placed on ice. The following reagents were added on ice: 4 μ l of 5 \times first strand buffer (250 mM TRIS-HCl (pH8.3), 375 mM KCl, 15 mM MgCl₂), 2 μ l of 0.1M DTT, 10 mM dNTP (nucleotide triphosphates) mix and 1 μ l of DEPC treated water. The reaction was incubated at 42° C. for 5 minutes. Finally, 5 μ l of Superscript RT II was added and incubated at 42° C. for 2 more hours. The reaction was terminated on ice.

Second Strand Synthesis

The first strand product was adjusted to 93 μ l with water and the following reagents were added on ice: 30 μ l of 5 \times 2nd strand buffer (5 \times concentration (in mM): 100 mM TRIS-HCl (pH6.9), 450 mM KCl, 23 mM MgCl₂, 0.75 mM β -NAD⁺, 50 mM (NH₄)₂SO₄), 3 μ l of 10 mM dNTP (nucleotide triphosphates), 1 μ l *E. coli* DNA ligase (10 units), 1 μ l RNase H (2 units), 4 μ l DNA pol I (10 units)). The reaction was incubated at 16° C. for 2 hours. The DNA from second strand synthesis was treated with T4 DNA polymerase and placed at 16° C. to blunt the DNA ends. The double stranded cDNA was extracted with 150 μ l of a mixture of phenol and chloroform (1:1, v:v) and precipitated with 0.5 volumes of 7.5 M NH₄OAc and 2 volumes of absolute ethanol. The pellet was washed with 70% ethanol and dried down at 37° C. to remove the residual ethanol. The double stranded DNA pellet was resuspended in 25 μ l of water and the following reagents were added; 10 μ l of 5 \times T4 DNA ligase buffer, 10 μ l of Sal1 adapters and 5 μ l of T4 DNA ligase. The ingredients were mixed gently and ligated overnight at 16° C. The ligation mix was extracted with phenol:chloroform:isoamyl alcohol, vortexed thoroughly and centrifuged at room temperature for 5 minutes at

14,000×g to separate the phases. The aqueous phase was transferred to a new tube and the volume adjusted to 100 µl with water. The purified DNA was size selected on a chromaspin 1000 column (Clontech) to eliminate the smaller cDNA molecules. The double stranded DNA was digested with NotI restriction enzyme for 3–4 hours at 37° C. The restriction digest was electrophoresed on a 0.8% low melt agarose gel. The cDNA in the range of 1–5 kb was cut out and purified using Gelzyme (Invitrogen). The product was extracted with phenol:chloroform and precipitated with NH₄OAc and absolute ethanol. The pellet was washed with 70% ethanol and resuspended in 10 µl of water.

Ligation of cDNA to the Vector

The cDNA was split up into 5 tubes (2 µl each) and the ligation reactions were set up by adding 4.5 µl of water, 2 µl of 5×ligation buffer, 1 µl of p-Sport vector DNA (cut with Sal-1/NotI and phosphatase treated) and 0.5 µl of T4 DNA ligase. The ligation was incubated at 40° C. overnight.

Introduction of Ligated cDNA into *E. coli* by Electroporation

The ligation reaction volume was adjusted to a total volume of 20 µl with water. Five milliliters of yeast tRNA, 12.5 ml of 7.5M NH₄OAc and 70 ml of absolute ethanol (–20° C.) was added. The mixture was vortexed thoroughly, and immediately centrifuged at room temperature for 20 minutes at 14000×g. The pellets were washed in 70% ethanol and each pellet was resuspended in 5 ml of water. All 5 ligations (25 ml) were pooled and 100 µl of DH10B electro-competent cells (Life Technologies) were electroporated with 1 ml of DNA (total of 20 electroporations), then plated out on ampicillin plates to determine the number of recombinants (cfu) per microliter. The entire library was seeded into 2 liters of Super Broth and maxipreps were made using Promega Maxi Prep kit and purified on cesium chloride gradients.

EXAMPLE 2

Library Screening/Human Calcium Channel Alpha1G-c Generation

Human Thalamus Library Screening

One microliter aliquots of the human thalamus library were electroporated into Electromax DH10B cells (Life Technologies). The volume was adjusted to 1 ml with SOC media and incubated for 60 minutes at 37° C. with shaking. The library was then plated out on 150 cm² plates containing LB to a density of 20000 colonies per plate. These cultures were grown overnight at 37° C.

A human calcium channel alpha1G-c probe was generated by polymerase chain reaction using the following primer pair:

SEQ.ID.NO.:1 5' oligo (18341F) 5' GCACTGCCAGTGGC-CGAGGG

SEQ.IN.NO.:2 3' oligo (18747R): 5' _CCATGGCGATGGTGATGCAG

The probe was generated by PCR using regular PCR conditions using 5' and 3' probe oligos (bOOng each) and 10 ng of diluted miniprep DNA. The resulting 274 bp fragment was run on 1% agarose gel and purified using GENECLAN kit (Bio 101, Inc.). About 100 ng of the purified probe was labeled with alpha 32P using oligolabeling kit from Pharmacia and the labeled DNA was purified with S-200 columns (Pharmacia).

The library colonies were lifted on Protran nitrocellulose filters (Schleicher & Schuel) and the DNA was denatured in 1.5 M NaCl, 0.5 M NaOH. The filter disks were neutralized with 1.5 M NaCl, 0.5 M Tris-HCl, pH 7.5 and then UV crosslinked to the membrane using a UV-Stratalinker (Stratagene). The filters were washed several times in wash solution (50 mM Tris-HCl, pH 8.0; 1 M NaCl; 1 mM EDTA;

0.1% SDS) at room temperature. Then the disks were incubated in 1×southern pre-hybridization buffer (5'-3' Inc) containing 50% formamide and 100 µg/ml of sheared salmon sperm DNA (5'-3' Inc) for 6 hours at 42 C. Finally, hybridization was performed overnight at 42 C. in 1×hybridization buffer (5'-3') containing 50% formamide, 100 ng of sheared salmon sperm DNA in the presence of labeled probe (5×10⁵ to 1×10⁶ cpm/ml of hybridization buffer).

The disks were washed once in 2×SSC, 0.2% SDS at room temperature for 30 minutes, once in 0.2×SSC, 0.1%SDS at 50 C. for 30 minutes, once in 0.2×SSC, 0.1%SDS at 55 C. for 30 minutes and once in 0.2×SSC, 0.1% SDS at 60 C. for 15 minutes. The membranes were then placed on sheets of filter paper, wrapped in the Saran Wrap and exposed to the film at –20 C. overnight.

Positive clones were identified and collected by coring the colonies from the original plate. The colonies were incubated in 2 ml of LB for 2 hours at 37° C. Dilutions of the cultures were plated onto LB agar plates and the filter-lifting, hybridizing, washing, colony-picking procedure was repeated. Individual clones from the second screen were picked and digested with EcoRI/NotI to determine the size of the inserts, and the inserts were sequenced.

Three different clones between 3–5kb in length were identified with open reading frames. These were digested with EcoR₁/XhoI and XhoI/NotI. These two pieces that were 4.2 kb and 3.2 kb were subjected to a 3 way ligation using an aliquot of pSport-1 vector that was cut with EcoR₁ and NotI and purified on a low melting point agarose gel. The ligated circular plasmid DNA was transformed into DH5 alpha bacterial cells from Gibco BRL. A few clones were picked and the entire 7.4 kb sequence was reconfirmed. A maxiprep of the plasmid DNA was obtained using the Promega kit. This DNA was further digested with EcoR₁ and Not 1 and the 7.4 kb was inserted into the expression vector pGEM HE . Large-scale preparation of DNA was done using a MEGA prep kit (Promega.).

EXAMPLE 3

Cloning Human Calcium Channel Alpha1G-c cDNA into a Mammalian Expression Vector

The human calcium channel alpha1G-c cDNAs (collectively referred to as hCaChalpha1G-c) were cloned into the mammalian expression vector pcDNA3.1/Zeo(+). The plasmid DNA in p-Sport vector was digested with Not I and EcoR₁ (NEB) to create cohesive ends. The product was purified by a low melting agarose gel electrophoresis. The pcDNA3.1/Zeo(+) vector was digested with EcoR₁ and NotI enzymes and subsequently purified on a low melt agarose gel. The linear vector was used to ligate to the human calcium channel alpha1G-c cDNA inserts.

EXAMPLE 4

Construction of a Stable Cell Line Expressing the Human Alpha1G-c

Recombinants were isolated, designated human calcium channel alpha1G-c, and are used to transfect mammalian cells (HEK293, COS-7 or CHO-K1 cells) using the Effectene non-liposomal lipid based transfection kit (Quiagen). Stable cell clones are selected by growth in the presence of zeocin. Single zeocin resistant clones are isolated and shown to contain the intact human calcium channel alpha1G-c gene. Clones containing the human calcium channel alpha1G-c cDNAs are analyzed for human calcium channel alpha1G-cprotein expression. Recombinant plasmids containing human calcium channel alpha1G-c encoding DNA are used to transform the mammalian COS or CHO cells or HEK293 cells.

Cells expressing human calcium channel $\alpha 1G$ -c, stably or transiently, are used to test for expression of human calcium channel $\alpha 1G$ -c activity. These cells are used to identify and examine other compounds for their ability to modulate, inhibit or activate the human calcium channel $\alpha 1G$ -c.

Cassettes containing the human calcium channel $\alpha 1G$ -c cDNA in the positive orientation with respect to the promoter are ligated into appropriate restriction sites 3' of the promoter and identified by restriction site mapping and/or sequencing. These cDNA expression vectors are introduced into fibroblastic host cells for example COS-7 (ATCC# CRL1651), and CV-1 tat [Sackevitz et al., Science 238: 1575 (1987)], 293, L (ATCC# CRL6362) by standard methods including but not limited to electroporation, or chemical procedures (cationic liposomes, DEAE dextran, calcium phosphate). Transfected cells and cell culture supernatants are harvested and analyzed for human calcium channel $\alpha 1G$ -c expression as described herein.

All of the vectors used for mammalian transient expression can be used to establish stable cell lines expressing human calcium channel $\alpha 1G$ -c. Unaltered human calcium channel $\alpha 1G$ -c receptor cDNA constructs cloned into expression vectors are expected to program host cells to make human calcium channel $\alpha 1G$ -c protein. The transfection host cells include, but are not limited to, CV-1-P [Sackevitz et al., Science 238: 1575 (1987)], tk-L [Wigler, et al. Cell 11: 223 (1977)], NS/O, and dHFr-CHO [Kaufman and Sharp, J. Mol. Biol. 159: 601, (1982)].

Human calcium channel $\alpha 1G$ -c cDNA constructs are also ligated into vectors containing amplifiable drug-resistance markers for the production of mammalian cell clones synthesizing the highest possible levels of human calcium channel $\alpha 1G$ -c. Following introduction of these constructs into cells, clones containing the plasmid are selected with the appropriate agent, and isolation of an over-expressing clone with a high copy number of plasmids is accomplished by selection in increasing doses of the agent.

Co-transfection of any vector containing human calcium channel $\alpha 1G$ -c cDNA with a drug selection plasmid including, but not limited to G418, aminoglycoside phosphotransferase; hygromycin, hygromycin-B phosphotransferase; APRT, xanthine-guanine phosphoribosyl-transferase or zeocin, will allow for the selection of stably transfected clones. Levels of human calcium channel $\alpha 1G$ -c are quantitated by the assays described herein (EXAMPLE 6).

The expression of recombinant human calcium channel $\alpha 1G$ -c is achieved by transfection of full-length human calcium channel $\alpha 1G$ -c cDNA into a mammalian host cell.

EXAMPLE 5

Characterization of Functional Protein Encoded by pCaCh $\alpha 1G$ -c in *Xenopus* Oocytes

Xenopus laevis oocytes were prepared and injected using standard methods previously described and known in the art (Fraser, S. P. et al. (1993)). Ovarian lobes from adult female *Xenopus laevis* (Nasco, Fort Atkinson, Wis.) were teased apart, rinsed several times in nominally Ca-free saline containing: 82.5 mM NaCl, 2.5 mM KCl, 1 mM MgCl₂, 5 mM HEPES, adjusted to pH 7.0 with NaOH (OR-2), and gently shaken in OR-2 containing 0.2% collagenase Type 1 (ICN Biomedicals, Aurora, Ohio) for 2-5 hours. When approximately 50% of the follicular layers were removed, Stage V and VI oocytes were selected and rinsed in media consisting of 75% OR-2 and 25% ND-96. The ND-96 contained: 100 mM NaCl, 2 mM KCl, 1 mM MgCl₂, 1.8

mM CaCl₂, 5 mM HEPES, 2.5 mM Na pyruvate, gentamicin (50 ug/ml), adjusted to pH 7.0 with NaOH. The extracellular Ca²⁺ was gradually increased and the cells were maintained in ND-96 for 2-24 hours before injection. For in vitro transcription, pGEM HE which had been modified to contain the multiple cloning site from pSPORT (Liman, E. R. et al. (1992)) containing human calcium channel $\alpha 1G$ -c was linearized with NotI and transcribed with T7 RNA polymerase (Promega) in the presence of the cap analog m7G(5')ppp(5')G. The human $\alpha 1G$ -c contained its natural Kozak sequence. The synthesized cRNA was precipitated with ammonium acetate and isopropanol, and resuspended in 50 μ l nuclease-free water. cRNA was quantified using formaldehyde gels (1% agarose, 1xMOPS, 3% formaldehyde) against RNA markers (Gibco BRL, 0.24-9.5 Kb).

Oocytes were injected with 50 nl of the human calcium channel $\alpha 1G$ -c cRNA (about 600 ng). Control oocytes were injected with 50 nl of water. Oocytes were incubated in ND-96 before analysis for expression of the human calcium channel $\alpha 1G$ -c. Incubations and collagenase digestion were carried out at room temperature. Injected oocytes were maintained in 48 well cell culture clusters (Costar, Cambridge, Mass.) at 18° C. Whole cell agonist-induced currents were measured 3-6 days after injection with a conventional two-electrode voltage clamp (GeneClamp500, Axon Instruments, Foster City, Calif.) using standard methods previously described and known in the art (Dascal, N. (1987)). The microelectrodes were filled with 3 M KCl, which had resistances of 1 and 2 M Ω . Cells were continuously perfused with ND96 at 2-5 ml/min at room temperature unless indicated. In some experiments, cells were bathed in a 40 mM Ba saline containing (in mM): 40 BaCl₂, 2 KCl, 36 TEA-Cl, 5 4-AP and 5 HEPES, pH 7.6. Membrane voltage was clamped at -100 mV unless indicated.

Depolarizing voltage steps elicited inward currents in oocytes that had been injected with RNA transcribed from the cloned human calcium channel $\alpha 1G$ -c cDNA as shown in FIGS. 4a,b. In some experiments in which oocytes expressed large outward currents and slowly activating inward currents at negative potentials (activation of endogenous Ca-activated Cl currents), oocytes were bathed in 40 mM Ba saline. Due to effects of Ba²⁺ on surface charge screening (Wilson et al., 1983), we usually used more physiological conditions (2 mM extracellular Ca²⁺; ND96).

FIG. 4a shows a representative family of current traces elicited by depolarizing pulses applied to the oocyte. Inward Ba²⁺ currents activated slowly near threshold potentials and with larger depolarizing voltage pulses, the currents activated more quickly and inactivated, producing a signature "criss-cross" pattern for classical T-type currents (Randall and Tsien, 1997). Water-injected oocytes had no detectable inward currents. Peak currents recorded in 2 mM extracellular Ca²⁺ were -380 \pm -170 nA (n=9), similar to that observed with Ba²⁺ as the charge carrier (-240 \pm -20 nA; n=8). The threshold voltage recorded in ND96 was about -59 mV (n=9). The voltage that elicited maximal currents was -29 \pm -5 mV (n=9). The voltage at which currents reversed sign was +29 \pm -5 mV (n=4). The time to peak from the onset of the voltage pulse was 5.2 \pm -2 msec (n=9). In 40 mM Ba²⁺ solution, the voltage dependence of activation was shifted slightly along the voltage axis (Huguenard, 1996; Perez-Reyes et al., 1998). The voltage eliciting peak currents was -33 \pm -2 mV (n=8). The time to peak response was similar to that recorded in 2 mM Ca²⁺ (4.8 \pm -0.3 msec).

Steady state inactivation (FIGS. 4c,d) was studied by applying 4 sec long prepulses followed by a test pulse to -30

mV to measure channel availability. In some experiments a 5 msec repolarization pulse to -100 mV was performed to close any channels still open at the end of the 4 sec pulse. Results were similar and combined. Similar $V_{0.5}$ for inactivation for the cloned mouse $\alpha 1G$ (AJ012569 contains the insert observed in the present invention in intracellular loop II-III as well as an extra 18 amino acid insert in intracellular loop between domains III-IV) expressed in HEK293 cells were obtained in Ca^{2+} and Ba^{2+} salines (Klugbauer et al., 1999). FIG. 4c shows representative current traces recorded during the test pulse. The percent of maximum response was calculated, plotted as a function of the prepulse potential and fit with a Boltzmann equation (FIG. 4d). Inactivation of human $\alpha 1G$ -c occurred at sub-threshold voltages and displayed a steep voltage dependence (slope -4.9 [-6.0 to -3.8], $n=7$). The voltage dependence of inactivation occurred at -67 mV with 95% confidence interval of -68.3 to -65.8 mV ($n=7$ experiments; CaSOS). The voltage dependence of inactivation was similar when recorded in 40 mM Ba^{2+} (-71+/-5 mV, $n=5$).

A defining feature of T-type calcium currents is that they deactivate relatively slowly compared to HVA calcium currents, producing slowly decaying tail currents after a depolarizing pulse. A 5 msec voltage step to -30 mV was followed by a step to -100 mV. The tau for current deactivation was 2.2+/-0.4 msec ($n=3$), similar to values reported for T-type currents.

The pharmacological characterization of human $\alpha 1G$ -c expressed in *Xenopus* oocytes was determined for mibefradil, Ni^{2+} , Cd^{2+} , amiloride and ethosuximide. The effect of the indicated concentrations of mibefradil on peak T-currents was determined. Mibefradil was bath applied to oocytes expressing human calcium channel $\alpha 1G$ -c cRNA (FIG. 5). Shown are 1-3 concentrations tested on 7 individual oocytes. The IC_{50} was 2.5 μM with a 95% confidence interval of 1.3 to 4.9 μM . Oocytes were bathed in ND96,

The present invention was relatively insensitive to Ni^{2+} blockade, similar to that observed for the rat $\alpha 1G$ (AJ027984) (Perez-Reyes et al., 1998). 200 μM $NiCl_2$ blocked the peak current by 25+/-6% ($n=3$); in the same cell, 1 mM $NiCl_2$ blocked about twice the current blocked by 200 μM Ni^{2+} . Oocytes were voltage clamped at -100 mV between test pulses. Cd^{2+} (100 μM) blocked T-currents by 44+/-9% ($n=3$).

The present invention was sensitive to amiloride block. 500 μM amiloride blocked peak currents by only 23+/-4% ($n=4$), similar to the block observed at rat spinal motoneurons (Huguenard, 1996). This concentration would completely block some T-type calcium currents (e.g., human $\alpha 1H$; see Background). Oocytes were maintained at -100 mV between voltage pulses and similar results were obtained for oocytes bathed in ND96 and Ba^{2+} salines.

The present invention was sensitive to block by the antiepileptic ethosuximide. 600 μM ethosuximide (Sigma), within the range of therapeutically relevant concentrations for the treatment of absence epilepsy (see Background), reversibly blocked peak currents by 26+/-3% ($n=3$). Oocytes were maintained at -100 mV between voltage pulses and similar results were obtained for oocytes bathed in ND96 and Ba^{2+} salines. Human $\alpha 1H$ currents are blocked only ~7% by 300 μM ethosuximide (WO 99/28342).

Interestingly, the chloride channel blocker NPPB (5-Nitro-2-(3-phenylpropylamino)benzoic acid) blocked human $\alpha 1G$ -c currents expressed in oocytes. 20, 100 and 200 μM NPPB blocked 22+/-6% ($n=3$), 55+/-7% ($n=3$), and

89+/-7% ($n=3$), respectively. Another chloride channel blocker 9-AC (anthracene-9-carboxylic acid, Sigma) was less effective in blocking T-currents; 100 μM 9-AC blocked peak currents by 30+/-3% ($n=4$). DIDS (4,4'-diisothiocyanatostilbene-2,2'-disulfonic acid (Sigma); 100 μM) and niflumic acid (100 μM) had no effect on peak human $\alpha 1G$ -c currents. DIDS and niflumic acid blocked the current by 16+/-13% ($n=3$) and 0+/-2% ($n=3$), respectively.

EXAMPLE 6

Characterization of Human Calcium Channel $\alpha 1G$ -c in Human HEK 293 Cell Line

Human HEK293 cells are transfected with human calcium channel $\alpha 1G$ -c pCaCh $\alpha 1G$ c (EXAMPLE 4). Transient transfections 1 μg of pCaCh $\alpha 1G$ per 10^6 cells per 100 mm dish are performed using the Effectene transfection kit (Quiagen; 301425). Three days after transfection, cells are plated onto 96-well plates (Biocoat, poly-D-lysine coated black/clear plate; Becton Dickinson part #354640). After one day, wells are rinsed with F12/DMEM, then incubated in Fluo-4 (2 μM) with Pluronic acid (20%, 40 μl used in 20 mls total volume) for 1 hour at room temperature. Plates are assayed using the FLIPR (Molecular Devices, FL-101). Cells are challenged with elevated K^+ to achieve a final concentrations of 10, 25 and 43 mM K^+ (applied in 40 μl added to 80 μl at a velocity of 50 $\mu l/sec$). Transfections with vector alone are tested as controls. The basal buffer contains (in mM): 123 NaCl, 2 KCl, 1 $MgCl_2$, 2 $CaCl_2$, 15 glucose and 20 HEPES, pH 7.4.

Cells stably expressing the human $\alpha 1G$ -c are plated onto 96-well plates (Biocoat, poly-D-lysine coated black/clear plate; Becton Dickinson part #354640) and grown to confluence. Wells are rinsed with F12/DMEM, then incubated in Fluo-4 (2 μM) with Pluronic acid (20%, 40 μl used in 20 mls total volume) for 1 hour at room temperature. Plates are assayed using the FLIPR (Molecular Devices, FL-101). Cells are challenged with elevated K^+ (in 40 μl added to 80 μl at a velocity of 50 $\mu l/sec$).

The whole cell patch clamp technique (Hamill, O. P. et al. (1981)) is used to record ligand-induced currents from HEK293 stably expressing human calcium channel $\alpha 1G$ -c maintained for >1 day on 12 mm coverslips. Cells are visualized using a Nikon Diaphot 300 with DIC Nomarski optics. Cells are continuously perfused in a physiological saline (~0.5 ml/min) unless otherwise indicated. The standard physiological saline ("CaCh physiological saline (CaChPS") contains: 15 mM $BaCl_2$, 150 mM CholineCl, 1 mM $MgCl_2$ and 10 mM HEPES (pH 7.3, 325 mOsm as measured using a Wescor 5500 vapor-pressure (Wescor, Inc., Logan, Utah). Recording electrodes are fabricated from borosilicate capillary tubing (R6; Garner Glass, Claremont, Calif.), the tips are coated with dental periphery wax (Miles Laboratories, South Bend, Ind.), and have resistances of 1-2 M Ω when containing intracellular saline: 135 mM CsCl, 10 mM EGTA, 1 mM $MgCl_2$, 10 mM HEPES (pH 7.4, with TEA-OH, 290 mOsm). Current and voltage signals are detected and filtered at 2 kHz with an Axopatch ID patch-clamp amplifier (Axon Instruments, Foster City, Calif.), digitally recorded with a DigiData 1200B laboratory interface (Axon Instruments), and PC compatible computer system and stored on magnetic disk for off-line analysis. Data acquisition and analysis are performed with PClamp software.

29

EXAMPLE 7

Pimgar Structure Of the Human Calcium Channel Alpha1G-c Protein

The nucleotide sequences of human calcium channel alpha1G-c revealed single large open reading frame of about 6819 base pairs encoding 2273 amino acids. The cDNAs have 5' and 3'-untranslated extensions of about 511 and about 397 nucleotides for human calcium channel alpha1G-c, respectively. The first in-frame methionine was designated as the initiation codon for an open reading frame that predicts a human calcium channel alpha1G-c protein with an estimated molecular mass (M_r) of about 251.8 kDa.

The predicted human calcium channel alpha1G-c protein was aligned with nucleotide and protein databases and found to be similar to the human alpha1G "a" isoform (accession #AF126966) with the exception that the sequence presented herein contains a 23 amino acid insert in the second intracellular loop between domains I and II. The insert contains a putative CKII phosphorylation site at S971. This 23 amino acid insert is 91 and 87% identical to the homologous sequence in rat (AF125161) and mouse (AJ012569), respectively. However, this insert is not present in another rat alpha1G isoform (AF027984) which is the ortholog to the present invention in regard to the remainder of the sequence. The putative casein kinase II phosphorylation site in this insert in the present invention is not conserved in rat or mouse.

There are 8, 23, 15 and 12 putative PKA (ie., R/K R/K x T/S), PKC (ie., S/T x K/R), casein kinase II (CKII; ie. S/T xx D/E) and MGCK (mammary gland casein kinase; ie., S x E) phosphorylation sites, respectively. There are 8 potential N-linked glycosylation sites. There are no putative tyrosine phosphorylation motifs (ie., R/K x x x D x x Y) in predicted intracellular domains.

EXAMPLE 8

Cloning Human Calcium Channel Alpha1G-c cDNA into *E. coli* Expression Vectors

Recombinant human calcium channel alpha1G-c is produced in *E. coli* following the transfer of the human calcium channel alpha1G-c expression cassette into *E. coli* expression vectors, including but not limited to, the pET series (Novagen). The pET vectors place human calcium channel alpha1G-c expression under control of the tightly regulated bacteriophage T7 promoter. Following transfer of this construct into an *E. coli* host that contain a chromosomal copy of the T7 RNA polymerase gene driven by the inducible lac promoter, expression of human calcium channel alpha1G-c is induced when an appropriate lac substrate (IPTG) is added to the culture. The levels of expressed human calcium channel alpha1G-c are determined by the assays described herein.

The cDNA encoding the entire open reading frame for human calcium channel alpha1G-c is inserted into the NdeI site of pET [16]11a. Constructs in the positive orientation are identified by sequence analysis and used to transform the expression host strain BL21. Transformants are then used to inoculate cultures for the production of human calcium channel alpha1G-c protein. Cultures may be grown in M9 or ZB media, whose formulation is known to those skilled in the art. After growth to an $OD_{600}=1.5$, expression of human calcium channel alpha1G-c is induced with 1 mM IPTG for 3 hours at 37° C.

30

EXAMPLE 9

Cloning Human Calcium Channel Alpha1G-c cDNA into a Baculovirus Expression Vector for Expression in Insect Cells

Baculovirus vectors, which are derived from the genome of the AcNPV virus, are designed to provide high level expression of cDNA in the Sf9 line of insect cells (ATCC CRL #1711). Recombinant baculoviruses expressing human calcium channel alpha1G-c cDNA is produced by the following standard methods (In Vitrogen Maxbac Manual): the human calcium channel alpha1G-c cDNA constructs are ligated into the polyhedrin gene in a variety of baculovirus transfer vectors, including the pAC360 and the BlueBac vector (In Vitrogen). Recombinant baculoviruses are generated by homologous recombination following co-transfection of the baculovirus transfer vector and linearized AcNPV genomic DNA [Kitts, P. A., Nuc. Acid. Res. 18: 5667 (1990)] into Sf9 cells. Recombinant pAC360 viruses are identified by the absence of inclusion bodies in infected cells and recombinant pBlueBac viruses are identified on the basis of β -galactosidase expression (Summers, M. D. and Smith, G. E., Texas Agriculture Exp. Station Bulletin No. 1555). Following plaque purification, human calcium channel alpha1G-c expression is measured by the assays described herein.

The cDNA encoding the entire open reading frame for human calcium channel alpha1G-c is inserted into the BamHI site of pBlueBacII. Constructs in the positive orientation are identified by sequence analysis and used to transfect Sf9 cells in the presence of linear AcNPV mild type DNA.

Authentic, active human calcium channel alpha1G-c is found in the cytoplasm of infected cells. Active human calcium channel alpha1G-c is extracted from infected cells by hypotonic or detergent lysis.

EXAMPLE 10

Cloning Human Calcium Channel Alpha1G-c cDNA into a Yeast Expression Vector

Recombinant human calcium channel alpha1G-c is produced in the yeast *S. cerevisiae* following insertion of the optimal human calcium channel alpha1G-c cDNA cistron into expression vectors designed to direct the intracellular or extracellular expression of heterologous proteins. In the case of intracellular expression, vectors such as EmBLYex4 or the like are ligated to the human calcium channel alpha1G-c cistron [Rinas, U. et al., Biotechnology 8: 543-545 (1990); Horowitz B. et al., J. Biol. Chem. 265: 4189-4192 (1989)]. For extracellular expression, the human calcium channel alpha1G-c cistron is ligated into yeast expression vectors which fuse a secretion signal (a yeast or mammalian peptide) to the NH₂ terminus of the human calcium channel alpha1G-c protein [Jacobson, M. A., Gene 85: 511-516 (1989); Riett L. and Bellon N. Biochem. 28: 2941-2949 (1989)].

These vectors include, but are not limited to pAVE1>6, which fuses the human serum albumin signal to the expressed cDNA [Steep O. Biotechnology 8: 42-46 (1990)], and the vector pL8PL which fuses the human lysozyme signal to the expressed cDNA [Yamamoto, Y., Biochem. 28: 2728-2732]. In addition, human calcium channel alpha1G-c is expressed in yeast as a fusion protein conjugated to ubiquitin utilizing the vector pVEP [Ecker, D. J., J. Biol. Chem. 264: 7715-7719 (1989), Sabin, E. A., Biotechnology 7: 705-709 (1989), McDonnell D. P., Mol. Cell Biol. 9: 5517-5523 (1989)]. The levels of expressed human calcium channel alpha1G-c are determined by the assays described herein.

EXAMPLE 11

Purification of Recombinant Human Calcium Channel Alpha1G-c

Recombinantly produced human calcium channel alpha1G-c may be purified by antibody affinity chromatography.

Human calcium channel alpha1G-c antibody affinity columns are made by adding the anti-human calcium channel alpha1G-c antibodies to Affigel-10 (Bio-Rad), a gel support that is pre-activated with N-hydroxysuccinimide esters such that the antibodies form covalent linkages with the agarose gel bead support. The antibodies are then coupled to the gel via amide bonds with the spacer arm. The remaining activated esters are then quenched with 1M ethanolamine HCl (pH 8). The column is washed with water followed by 0.23 M glycine HCl (pH 2.6) to remove any non-conjugated antibody or extraneous protein. The column is then equilibrated in phosphate buffered saline (pH 7.3) together with appropriate membrane solubilizing agents such as detergents and the cell culture supernatant or cell extract containing solubilized human calcium channel alpha1G-c is slowly passed through the column. The column is then washed with phosphate-buffered saline together with detergents until the optical density (A280) falls to background, then the protein is eluted with 0.23 M glycine-HCl (pH 2.6) together with detergents. The purified human calcium channel alpha1G-c protein is then dialyzed against phosphate buffered saline.

What is claimed is:

1. An isolated and purified DNA molecule that encodes human calcium channel alpha1G-c channel protein, comprising an amino acid sequence set forth in SEQ ID NO: 5.

2. The isolated and purified DNA molecule of claim 1, having a nucleotide sequence selected from a group consisting of SEQ ID NO: 3 and SEQ ID NO: 4.

3. An expression vector for expression of a human calcium channel alpha1G-c channel protein in a recombinant host, wherein said vector contains a recombinant nucleic acid molecule encoding human calcium channel alpha1G-c protein comprising an amino acid sequence set forth in SEQ ID NO: 5.

4. The expression vector of claim 3, wherein the expression vector contains a cloned nucleic acid molecule encoding human calcium channel alpha1G-c channel protein having a nucleotide sequence selected from a group consisting of SEQ ID NO: 3 and SEQ ID NO: 4.

5. A process for expression of human calcium channel alpha1G-c channel protein in a recombinant host cell, comprising:

(a) transferring the expression vector of claim 3 into suitable host cells; and

(b) culturing the host cells of step (a) under conditions which allow expression of the human calcium channel alpha1G-c channel protein from the expression vector.

6. A recombinant host cell containing a recombinantly cloned nucleic acid molecule encoding human calcium channel alpha1G-c channel protein comprising an amino acid sequence set forth in SEQ ID NO: 5.

7. The recombinant host cell of claim 6, wherein said nucleic acid molecule has a nucleotide sequence selected from a group consisting of SEQ ID NO: 3 and SEQ ID NO: 4.

(57) ABSTRACT

The invention provides TCCV-1 or TCCV-2 from human,
reagents related thereto including polynucleotides encoding
TCCV-1 or TCCV-2, purified polypeptides, and specific
antibodies. Methods of making and using these reagents, in
particular, methods for screening compounds which modu-
late TCCV-1 or TCCV-2 activity are provided. Also pro-
vided are methods of diagnosis and kits.

T-TYPE CALCIUM CHANNEL VARIANTS; COMPOSITIONS THEREOF; AND USES

RELATED APPLICATIONS

This U.S. patent application claims priority under 35 U.S.C. 119(e) to U.S. Provisional Application Serial No. 60/102,222, filed Sep. 29, 1998, incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

The present invention relates to nucleic acid and amino acid sequences of human T-type calcium channel variants and the use of these sequences in diagnosis of disease states associated with pain and for use as targets for screening therapeutic compounds useful in the treatment of disease states associated with pain.

BACKGROUND OF THE INVENTION

Voltage-gated calcium channels can be divided into high- and low-threshold types. The high-threshold channels include the dihydropyridine-sensitive L-type, the ω -conotoxin GVIA-sensitive N-type and ω -agatoxin IVA-sensitive P-type. Depending on the tissue, these channel subtypes consist of α_1 , $\alpha_2\delta$, β and γ subunits. (Perez-Reyes and Schneider (1995) *Kid. Int.* 48:1111-1124.) To date, only one type of low-threshold calcium channel is known, the T-type calcium channel.

T-type calcium channels have hyperpolarized steady-state inactivation characteristics, a low threshold for inactivation, small single channel conductance and display rapid inactivation kinetics. (Ertel and Ertel (1997) *Trends Pharmacol. Sci.* 18:37-42.) The functional roles for T-type calcium channels in neurons include membrane depolarization, calcium entry and burst firing. (White et al. (1989) *Proc. Natl. Acad. Sci. USA* 86:6802-6806.) T-type calcium channels are found in many neurons of the central and peripheral nervous systems, including small and medium diameter neurons of the dorsal root ganglia (Scroggs and Fox (1992) *J. Physiol.* 445:639-658) and neurons in the thalamus. (Suzuki and Rogawski (1989) *Proc. Natl. Acad. Sci. USA* 86:7228-7232.)

Calcium currents have been found to be important in several neurological and muscular functions, e.g., pain transmission, cardiac pacemaker activity, etc. Improper functioning of these channels has been implicated in arrhythmias, chronic peripheral pain, improper pain transmission in the central nervous system, and epilepsy.

Anti-epileptic drugs are known to cause a reduction of the low-threshold calcium current (LTCC or T-type Ca^{2+} current) in thalamic neurons. (Coulter et al. (1989) *Ann. Neurol.* 25:582-593.) One such anti-epileptic compound, ethosuximide, has been shown to fully block T-type Ca^{2+} current in freshly dissected neurons from dorsal root ganglia (DRG neurons) of adult rats (Todorovic and Lingle (1998) *J. Neurophysiol.* 79:240-252), and may have limited efficacy in the treatment of abnormal, chronic pain syndromes that follow peripheral nerve damage.

Molecular cloning has revealed the cDNA and corresponding amino acid sequences of several different $\alpha 1$ subunits (α_{1A} , α_{1B} , α_{1C} , α_{1D} , α_{1E} , α_{1G} , α_{1H} , α_{1I} , and α_{1S}). While the cloned $\alpha 1$ subunits identified thus far correspond to several of the calcium channels found in cells, they do not account for all types of calcium conductance found in native cells.

The present invention relates to the discovery of human T-type calcium channel α_{1I} subunit variants that are useful

in diagnosis of disease states associated with the peripheral nervous system and for screening compounds that may be used in the treatment of mammals for these disease states.

SUMMARY OF THE INVENTION

The invention is based on the discovery of human T-type calcium channel α_{1I} subunit variants (TCCV-1 and TCCV-2), the polynucleotides encoding TCCV-1 or TCCV-2, and the use of these compositions in screening for compounds effective in treating disease states associated with peripheral pain, and the use of these compositions for diagnosis of these disease states. In particular, the present invention expression vectors, host cells, antibodies, diagnostic kits, and transgenic/knockout animals are provided.

The invention features an isolated polynucleotide encoding TCCV-1 or TCCV-2 polypeptides. The invention further provides an isolated polynucleotide, encoding a TCCV-1 or TCCV-2 polypeptide wherein the polynucleotide encodes an TCCV-1 or TCCV-2 polypeptide comprising the amino acid sequence of SEQ ID NO:2 or 4, respectively. In certain embodiments, the polynucleotide is detectably labeled or is complementary to the polynucleotide encoding a TCCV-1 or TCCV-2 polypeptide. The complementary polynucleotide can also be detectably labeled. In another embodiment, the polynucleotide comprises the nucleic acid sequence of SEQ ID NO:1 or 3.

The present invention encompasses an expression vector comprising the polynucleotide encoding SEQ ID NO:2 or 4. Also contemplated is a host cell comprising the polynucleotide encoding SEQ ID NO:2 or 4. The host cell can be a prokaryotic or eukaryotic cell. The invention further comprises a method of producing a TCCV-1 or TCCV-2 polypeptide comprising: culturing the host cell comprising the expression vector comprising the polynucleotide encoding SEQ ID NO:2 or 4 under conditions suitable for expression of the polypeptide; and recovering the polypeptide from the host cell.

The present invention also contemplates a method of detecting a polynucleotide encoding a TCCV-1 or TCCV-2 polypeptide in a sample containing nucleic acid material, comprising the steps of: contacting the sample with a polynucleotide which is the complement of the polynucleotide encoding SEQ ID NO:2 or 4, wherein the complement is detectably labeled, under conditions suitable for formation of a hybridization complex; and detecting the complex, wherein the presence of the complex is indicative of the presence of the polynucleotide encoding the polypeptide in the sample.

The present invention provides a diagnostic test kit comprising: the polynucleotide comprising SEQ ID NO:1 or 3; and instructions for conducting the diagnostic test.

The present invention encompasses a method of screening for a compound that modulates TCCV-1 or TCCV-2 activity comprising: contacting TCCV-1 or TCCV-2, or fragment thereof with the compound; and detecting modulation of TCCV-1 or TCCV-2 activity. In certain embodiments, the TCCV-1 or TCCV-2 is expressed on a cell or tissue or immobilized on a solid support. The compound can be an antagonist or agonist of TCCV-1 or TCCV-2 activity. In a further embodiment, the compound is ethosuximide or an analog thereof.

The present invention provides an isolated TCCV-1 or TCCV-2 polypeptide or fragment thereof. In certain embodiments, the polypeptide comprises the amino acid sequence of SEQ ID NO:2 or 4. The polypeptide is recombinantly produced or synthetically produced. The present

invention also provides an isolated antibody which specifically binds to the polypeptide of SEQ ID NO:2 or 4.

The present invention encompasses a transgenic nonhuman mammal comprising the polynucleotide encoding TCCV-1 or TCCV-2 polypeptide. The transgenic nonhuman mammal can also comprise the polynucleotide which is the complement of the polynucleotide encoding TCCV-1 or TCCV-2 which is capable of hybridizing to a polynucleotide encoding TCCV-1 or TCCV-2, thereby reducing expression of TCCV-1 or TCCV-2.

BRIEF DESCRIPTION OF FIGURES AND SEQUENCE IDENTIFIERS

FIGS. 1A-1F show the amino acid alignment between TCCV-1 (SEQ ID NO:2), TCCV-2 (SEQ ID NO:4), and rat T-type Calcium Channel subunit α_1 (GenBank Accession No. AAD17796; SEQ ID NO:5). Residues that differ between the rat and human sequences are indicated in bold.

FIGS. 2A-2C show the splicing differences between the 3' ends of TCCV-1 (nucleotides 5148 through 6015 of SEQ ID NO:1) or TCCV-2 (nucleotides 5148 through 6054 of SEQ ID NO:3), and GenBank Accession No. AF086827 (nucleotides 4927 through 5847 of SEQ ID NO:12). Downward pointing arrows indicate exon boundaries. Forward arrows indicate forward PCR primers (Primer Numbers 6352, 6344/88, 6495, and 6495/37). Reverse arrows indicate reverse or antisense PCR primers (Primer Number 6831). Nucleotide differences in the rat sequence which differ from the human PCR primer sequences are underlined.

FIG. 3 shows a 2.0% agarose gel of PCR products following 36 cycles of amplifications using various primers as shown in FIGS. 2A-2C on human brain cDNA. Lane 1 is a 100 bp ladder (Life Technologies, Bethesda, Md.); Lane 3 is the PCR product following amplification with forward primer 6352 and reverse primer 6831; Lane 4 is the PCR product following amplification with forward primer 6344/88 and reverse primer 6831; Lane 5 is the PCR product following amplification with forward primer 6495 and reverse primer 6831; and Lane 6 is the result of amplification with forward primer 6495/37 and reverse primer 6831.

SEQ ID NO:1 is the polynucleotide sequence for TCCV-1. SEQ ID NO:2 is the putative encoded polypeptide.

SEQ ID NO:3 is the polynucleotide sequence for TCCV-2. SEQ ID NO:4 is the putative encoded polypeptide.

SEQ ID NO:5 is the amino acid sequence of GenBank Accession No. AAD17796.

SEQ ID NO:6 through SEQ ID NO:11 are PCR primers used in assembly of full length TCCV-1 and TCCV-2.

SEQ ID NO:12 is the nucleic acid sequence of GenBank Accession No. AF086827.

DETAILED DESCRIPTION OF THE INVENTION

Before the present proteins, nucleotide sequences, and methods are described, it is to be understood that the present invention is not limited to the particular methodologies, protocols, cell lines, vectors, and reagents described, as these may vary. It is also understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not to limit the scope of the present invention.

The singular forms "a," "an," and "the" include plural reference unless the context clearly dictates otherwise.

All technical and scientific terms used herein have the same meanings as commonly understood by one of ordinary

skill in the art to which this invention pertains. The practice of the present invention will employ, unless otherwise indicated, conventional techniques of protein chemistry and biochemistry, molecular biology, microbiology and recombinant DNA technology, which are within the skill of the art. Such techniques are explained fully in the literature.

Although any machines, materials, and methods similar or equivalent to those described herein can be used to practice or test the present invention, the preferred machines, materials, and methods are now described. All patents, patent applications, and publications mentioned herein, whether supra or infra, are each incorporated by reference in its entirety.

Definitions

"TCCV" refers to the amino acid sequences of substantially purified TCCV-1 or TCCV-2 obtained from any species particularly mammalian species, including bovine, ovine, porcine, murine, equine, and preferably the human species, from any source, whether natural, synthetic, semi-synthetic, or recombinant.

"Agonist" refers to a molecule which, when bound to TCCV-1 or TCCV-2, or is within proximity of TCCV-1 or TCCV-2, modulates the activity of TCCV-1 or TCCV-2 by increasing or prolonging the duration of the effect of TCCV-1 or TCCV-2. Agonists can include proteins, nucleic acids, carbohydrates, organic compounds, inorganic compounds, or any other molecules which modulate the effect of TCCV-1 or TCCV-2.

An "allelic variant" as used herein, is an alternative form of the gene encoding TCCV-1 or TCCV-2. Allelic variants may result from at least one mutation in the nucleic acid sequence and may result in altered mRNAs or in a polypeptide whose structure or function may or may not be altered. Any given recombinant gene may have none, one, or several allelic forms. Common mutational changes which give rise to allelic variants are generally ascribed to natural deletions, additions, or substitutions of nucleotides. Each of these types of changes may occur alone, or in combination with the others, one or more times in a given sequence.

"Amplification" relates to the production of additional copies of a nucleic acid sequence. Amplification can be carried out using polymerase chain reaction (PCR) technologies or other methods well known in the art.

The term "analog" is used herein in the conventional pharmaceutical sense. In chemical terminology, an analog refers to a molecule that structurally resembles a referent molecule but which has been modified in a targeted and controlled manner to replace a certain substituent of the referent molecule with an alternate substituent other than hydrogen.

"Antagonist" refers to a molecule which, when bound to TCCV-1 or TCCV-2 or within close proximity, decreases the amount or the duration of the biological or immunological activity of TCCV-1 or TCCV-2. Antagonists may include proteins, nucleic acids, carbohydrates, antibodies, organic compounds, inorganic compounds, or any other molecules which exert an effect on TCCV-1 or TCCV-2 activity.

"Antibody" can be an intact molecule or fragments thereof, such as Fab, F(ab)₂, and Fv fragments, which are capable of binding an epitopic determinant. The antibody can be polyclonal, monoclonal, or recombinantly produced.

The terms "antigenic determinant" or "epitopic determinant" refer to the fragment of a molecule that makes contact with a particular antibody.

The term "antisense" refers to any composition containing nucleic acids which is complementary to the "sense" strand of a specific nucleic acid molecule. Antisense molecules

may be produced by any method including synthesis or transcription. Once introduced into a cell, the complementary nucleotides combine with natural sequences produced by the cell to form duplexes and to block either transcription or translation. The designation "negative" can refer to the antisense strand, and the designation "positive" can refer to the sense strand.

A "coding sequence" is a polynucleotide sequence that is transcribed into mRNA and translated into a polypeptide. The boundaries of the coding sequence are determined by a translation start codon at the 5'-terminus and a translation stop codon at the 3'-terminus. A coding sequence can include, but is not limited to, mRNA, cDNA, synthetic DNA, and recombinant polynucleotide sequences. Also included is genomic DNA where the coding sequence is interrupted by introns.

"Complementary" and "complementarity" refer to the natural binding of polynucleotides to other polynucleotides by base pairing. For example, the sequence "5' A-C-G-T 3'" will bind to the complementary sequence "3' T-G-C-A 5'." Complementarity between two single stranded molecules may be "partial," such that only some of the nucleic acids bind, or it may be "complete," such that total complementarity exists between the single stranded molecules.

A "composition comprising a given polynucleotide sequence" and a "composition comprising a given amino acid sequence" refer broadly to any composition containing the given polynucleotide or amino acid sequence.

The term "control elements" refers collectively to promoters, ribosome binding sites, polyadenylation signals, transcription termination sequences, upstream regulatory domains, enhancers, and the like, which collectively provide for the transcription and translation of a coding sequence in a host cell. Not all of these control sequences need always be present in a recombinant vector so long as the desired gene is capable of being transcribed and translated.

The phrase "correlates with expression of a polynucleotide" refers to the detection of the presence of nucleic acids, the same or related to a nucleic acid sequence encoding TCCV-1 or TCCV-2, e.g., by northern analysis or RT-PCR, is indicative of the presence of nucleic acids encoding TCCV-1 or TCCV-2 in a sample, and thereby is indicative of the expression of the transcript from the polynucleotide encoding TCCV-1 or TCCV-2.

The phrase "detectably labeled" as used herein means joining, either covalently or non-covalently to the polynucleotides, polypeptides, or antibodies of the present invention, a substance which provides for a detectable signal. A wide variety of labels and conjugation techniques are well known in the art. Suitable labels include radionuclides, e.g., ^{32}P , ^{35}S , ^3H , enzymes, substrates, cofactors, inhibitors, fluorescent moieties, chemiluminescent moieties, magnetic particles, and the like.

The phrase "disease state" means any disease, condition, symptom, or indication.

The term "expression" as used herein intends both transcriptional and translational processes, i.e., the production of messenger RNA and/or the production of protein therefrom.

The term "hybridization complex" refers to a complex formed between two nucleic acid sequences by virtue of the formation of hydrogen bonds between complementary bases. A hybridization complex may be formed in solution (conditions calculated by performing, e.g., C_{ot} or R_{ot}) or formed between one nucleic acid sequence present in solution and another nucleic acid sequence immobilized on a solid support (e.g., paper, membranes, filters, chips, pins, glass slides, or any other appropriate substrate to which cells or their nucleic acids have been fixed.)

An "isolated polynucleotide" that encodes a particular polypeptide refers to a polynucleotide that is substantially free of other nucleic acid molecules that do not encode the subject polypeptide; however, the molecule may include functionally and/or structurally conservative mutations as defined herein.

The term "modulate" refers to a change in the activity of TCCV-1 or TCCV-2. For example, modulation may cause an increase or a decrease in protein activity, binding characteristics, or any other biological, functional, or immunological properties of TCCV-1 or TCCV-2. The ability to modulate the activity of TCCV-1 or TCCV-2 can be exploited in assays to screen for organic, inorganic, or biological compounds which affect the above properties of TCCV-1 or TCCV-2.

"Nucleic acid" and "nucleic acid sequence" refer to a nucleotide, oligonucleotide, polynucleotide, or any fragment thereof. These phrases also refer to DNA or RNA of genomic or synthetic origin which may be single stranded or double stranded and may represent the sense of the antisense strand, a peptide nucleic acid (PNA), or any DNA-like or RNA-like material. In this context, "fragments" refer to those nucleic acids which, when translated, would produce polypeptides retaining some functional characteristic, e.g., antigenicity, or structural domain, e.g., ion channel domain, characteristic of the full-length polypeptide.

The terms "operably associated" and "operably linked" refer to functionally related but heterologous nucleic acid sequences. A promoter is operably associated or operably linked with a coding sequence if the promoter controls the translation or expression of the encoded polypeptide. While operably associated or operably linked nucleic acid sequences can be contiguous and in the same reading frame, certain genetic elements, e.g., repressor genes, are not contiguously linked to the sequence encoding the polypeptide but still bind to operator sequences that control expression of the polypeptide.

An "oligonucleotide" refers to a nucleic acid molecule of at least about 6 to 50 nucleotides, preferably about 15 to 30 nucleotides, and more preferably 20 to 25 nucleotides, which can be used in PCR amplification or in a hybridization assay. "Oligonucleotide" is substantially equivalent to the terms "amplimer," "primer," "oligomer," and "probe" as these terms are commonly defined in the art.

"Peptide nucleic acid" (PNA) refers to an antisense molecule or anti-gene agent which comprises an oligonucleotide of at least 5 nucleotides in length linked to a peptide backbone of amino acid residues ending in lysine. The terminal lysine confers solubility to the composition. PNAs preferentially bind complementary single stranded DNA or RNA and stop transcript elongation, and may be pegylated to extend their lifespan in the cell.

The phrases "percent identity" and "% identity" refers to the percentage of sequence similarity found by a comparison or alignment of two or more amino acid or nucleic acid sequences. Percent identity can be determined by a direct comparison of the sequence information between two molecules by aligning the sequences, counting the exact number of matches between the two aligned sequences, dividing by the length of the shorter sequence, and multiplying the result by 100. Readily available computer programs can be used to aid in the analysis, such as ALIGN, Dayhoff, M. O. in *Atlas of Protein Sequence and Structure* M. O. Dayhoff ed., 5 Suppl. 3:353-358, National Biomedical Research Foundation, Washington, D.C., which adapts the local homology algorithm of Smith and Waterman (1981) *Advances in Appl. Math.* 2:482-489, for peptide analysis.

Programs for determining nucleotide sequence identity are available in the Wisconsin Sequence Analysis Package, Version 8 (Genetics Computer Group, Madison, Wis.) for example, the BLAST, BESTFIT, FASTA, and GAP programs, which also rely on the Smith and Waterman algorithm. These programs are readily utilized with the default parameters recommended by the manufacturer and described in the Wisconsin Sequence Analysis Package referred to above. Other programs for calculating identity or similarity between sequences are known in the art.

"Recombinant host cells," "host cells," "cells," "cell lines," "cell cultures," and other such terms denoting cell lines cultured as unicellular entities refer to cells which can be, or have been, used as recipients for recombinant vectors or other transfer DNA, immaterial of the method by which the DNA is introduced into the cell or the subsequent disposition of the cell. The terms include the progeny of the original cell which has been transfected. Cells in primary culture as well as cells such as oocytes also can be used as recipients.

A "reporter gene" is a gene that, upon expression, confers a phenotype on a cell expressing the reporter gene, such that the cell can be identified under appropriate conditions. For example, the reporter gene may produce a polypeptide product that can be easily detected or measured in a routine assay. Suitable reporter genes known in the art which confer this characteristic include those that encode chloramphenicol acetyl transferase (CAT activity), β -galactosidase, luciferase, alkaline phosphatase, human growth hormone, fluorescent proteins, such as green fluorescent protein (GFP), and others. Indeed, any gene that encodes a protein or enzyme that can readily be measured, for example, by an immunoassay such as an enzyme-linked immunosorbent assay (ELISA) or by the enzymatic conversion of a substrate into a detectable product, and that is substantially not expressed in the host cells (specific expression with no background) can be used as a reporter gene to test for promoter activity. Other reporter genes for use herein include genes that allow selection of cells based on their ability to thrive in the presence or absence of a chemical or other agent that inhibits an essential cell function. Suitable markers, therefore, include genes coding for proteins which confer drug resistance or sensitivity thereto, or change the antigenic characteristics of those cells expressing the reporter gene when the cells are grown in an appropriate selective medium. For example, reporter genes include: cytotoxic and drug resistance markers, whereby cells are selected by their ability to grow on media containing one or more of the cytotoxins or drugs; auxotrophic markers by which cells are selected by their ability to grow on defined media with or without particular nutrients or supplements; and metabolic markers by which cells are selected for, e.g., their ability to grow on defined media containing the appropriate sugar as the sole carbon source. These and other reporter genes are well known in the art.

A "change in the level of reporter gene product" is shown by comparing expression levels of the reporter gene product in a cell exposed to a candidate compound relative to the levels of reporter gene product expressed in a cell that is not exposed to the test compound and/or to a cell that is exposed to a control compound. The change in level can be determined quantitatively for example, by measurement using a spectrophotometer, spectrofluorometer, luminometer, and the like, and will generally represent a statistically significant increase or decrease in the level from background. However, such a change may also be noted without quantitative measurement simply by, e.g., visualization, such as

when the reporter gene is one that confers the ability on cells to form colored colonies on chromogenic substrates.

The term "sample" is used in its broadest sense. A sample suspected of containing nucleic acids encoding TCCV-1 or TCCV-2, or fragments thereof, or TCCV-1 or TCCV-2 polypeptide may comprise a bodily fluid; an extract from a cell, chromosome, organelle, or membrane isolated from a cell; an intact cell; genomic DNA, RNA, or cDNA, in solution or bound to a substrate; a tissue; a tissue print; etc.

"Stringent conditions" refers to conditions which permit hybridization between polynucleotides and the claimed polynucleotides. Stringent conditions can be defined by salt concentration, the concentration of organic solvent, e.g., formamide, temperature, and other conditions well known in the art.

"Subject" means mammals and non-mammals. Mammals means any member of the Mammalia class including, but not limited to, humans, non-human primates such as chimpanzees and other apes and monkey species; farm animals such as cattle, horses, sheep, goats, and swine; domestic animals such as rabbits, dogs, and cats; laboratory animals including rodents, such as rats, mice, and guinea pigs; and the like. Examples of non-mammals include, but are not limited to, birds, and the like. The term "subject" does not denote a particular age or sex.

The term "substantially purified," when referring to a polypeptide, indicates that the polypeptide is present in the substantial absence of other similar biological macromolecules.

The term "transfection" refers to the insertion of an exogenous polynucleotide into a host cell, irrespective of the method used for the insertion, or the molecular form of the polynucleotide that is inserted. The insertion of a polynucleotide per se and the insertion of a plasmid or vector comprised of the exogenous polynucleotide are included. The exogenous polynucleotide may be directly transcribed and translated by the cell, maintained as a nonintegrated vector, for example, a plasmid, or alternatively, may be stably integrated into the host genome.

The term "transformed" refers to any known method for the insertion of foreign DNA or RNA sequences into a host prokaryotic cell. The term "transfected" refers to any known method for the insertion of foreign DNA or RNA sequences into a host eukaryotic cell. Such transformed or transfected cells include stably transformed or transfected cells in which the inserted DNA is rendered capable of replication in the host cell. They also include transiently expressing cells which express the inserted DNA or RNA for limited periods of time. The transformation or transfection procedure depends on the host cell being transformed. It can include packaging the polynucleotide in a virus as well as direct uptake of the polynucleotide, such as, for example, lipofection or microinjection. Transformation and transfection can result in incorporation of the inserted DNA into the genome of the host cell or the maintenance of the inserted DNA within the host cell in plasmid form. Methods of transformation are well known in the art and include, but are not limited to, viral infection, electroporation, lipofection, and calcium phosphate mediated direct uptake. "Treating" or "treatment" of a disease state includes: 1) preventing the disease state, i.e. causing the clinical symptoms of the disease state not to develop in a subject that may be exposed to or predisposed to the disease state, but does not yet experience or display symptoms of the disease state; 2) inhibiting the disease state, i.e., arresting the development of the disease state or its clinical symptoms; 3) or relieving the disease state, i.e., causing temporary or permanent regression of the disease state or its clinical symptoms.

A "variant" of TCCV-1 or TCCV-2 polypeptides refers to an amino acid sequence that is altered by one or more amino acid residues. The variant may have "conservative" changes, wherein a substituted amino acid has similar structural or chemical properties (e.g., replacement of leucine with isoleucine.) More rarely, a variant may have "nonconservative" changes (e.g., replacement of glycine with tryptophan.) Analogous minor variations may also include amino acid deletion or insertions, or both. Guidance in determining which amino acid variations may be substituted, inserted, or deleted without abolishing biological function may be found using programs well known in the art, for example, LASER-GENE software (DNASTAR).

The term "variant" when used in the context of a polynucleotide sequence, may encompass a polynucleotide sequence related to TCCV-1 or TCCV-2. This definition may include, for example "allelic" (as defined above), "splice," "species," "polymorphic," or "degenerate" variants. A splice variant may have significant identity to a reference molecule, but will generally have a greater or less number of polynucleotides due to alternate splicing of exons during mRNA processing. The corresponding polypeptide may possess additional functional domains or an absence of domains. Species variants are polynucleotide sequences that vary from one species to another. The resulting polypeptides generally will have significant amino acid identity to each other. A polymorphic variant is a variation in the polynucleotide sequence of a particular gene between individuals within a given species. Polymorphic variants may also encompass "single nucleotide polymorphisms" (SNPs) in which the polynucleotide sequence varies by one base. The presence of SNPs may be indicative of, for example, a certain population, a disease state, or a propensity for a disease state. A degenerate variant encompasses a multitude of polynucleotides which encode TCCV-1 or TCCV-2 polypeptides. The degenerate variants may occur naturally or may be produced synthetically. Synthetic degenerate variants are made in accordance with the standard triplet genetic code as applied to the polynucleotide sequence of naturally occurring TCCV-1 or TCCV-2, and all such variations are to be considered as being specifically disclosed.

A "vector" is a replicon in which another polynucleotide segment is attached, such as to bring about the replication and/or expression of the attached segment. The term includes expression vectors, cloning vectors, and the like.

The Invention

The present invention is based on the discovery of a human T-type calcium channel α_1 subunit variant (TCCV-1 or TCCV-2), the polynucleotides encoding TCCV-1 or TCCV-2, and the use of these compositions for screening compounds useful in the treatment or prevention of pain, including, but not limited to peripheral pain; peripheral neuropathies; pain caused by trauma or toxic compounds; diabetic neuropathy; cancer pain, and the like.

The molecules of the present invention were isolated by homology searching of the GenBank database using the rat T-type calcium channel α_1 subunit (see, e.g., Perez-Reyes et al. (1998) *Nature* 391:896-900; and GenBank Accession No. AF027984) and the human α_1 subunit. (See, e.g., Cribbs et al. (1998) *Circ. Res.* 83:103-109; and GenBank Accession No. AF051946.) Two genomic clones (GenBank Accession No. AL02231.9 and AL00871.6) from human chromosome 22 were identified as being homologous to the two subunits.

Through PCR extension and use of sequence analysis software, TCCV-1 and TCCV-2 were assembled. TCCV-1 is a 6816 bp polynucleotide (SEQ ID NO:1) encoding a

polypeptide of 2175 amino acid residues (SEQ ID NO:2). TCCV-2 is a 6855 bp polynucleotide (SEQ ID NO:3) encoding a polypeptide of 2188 amino acid residues (SEQ ID NO:4). FIGS. 1A-1F show an amino acid alignment between TCCV-1, TCCV-2, and the rat α_1 subunit (GenBank Accession No. AAD17796; SEQ ID NO:5). The overall sequence identity between TCCV-1 and AAD17796 is approximately 77%, with 93% identity from residues 1 through 1823 of SEQ ID NO:2. A unique fragment of SEQ ID NO:2 from about residue 1811 through about residue 2175 is useful, e.g., as an immunogenic polypeptide. The corresponding polynucleotide sequence from about nucleotide 5622 through about nucleotide 6716 of SEQ ID NO:1 is useful, e.g., as a hybridization probe. A unique fragment of SEQ ID NO:4 from about residue 1824 through about residue 2188 is useful, e.g., as an immunogenic polypeptide. The corresponding polynucleotide fragment from about nucleotide 5661 through about nucleotide 6755 is useful, e.g., as a hybridization probe.

PCR analysis was performed using forward primers spanning exons 31 and 32 of SEQ ID NO:1, 3, and 12 (Primer Number 6352 for SEQ ID NO:1 and 12, and Primer Number 6344/88 for SEQ ID NO:3) and exons 32 and 33 of SEQ ID NO:1, 3, and 12 (Primer Number 6495 for SEQ ID NO:1 and 3, and Primer Number 6495/37 for SEQ ID NO:12) in combination with a reverse primer (Primer Number 6831 for SEQ ID NO: 1, 3, and 12). The results are illustrated in FIG. 3. No PCR product was detected using forward Primer Number 6493/37 and reverse Primer Number 6831 (lane 6).

The invention also encompasses nucleic or amino acid variants of TCCV-1 or TCCV-2. A preferred variant is one which has at least about 80%, more preferably at least about 90%, and most preferably at least about 95% amino acid or nucleic acid identity to the corresponding TCCV-1 or TCCV-2 sequence, and which contains at least one functional or structural characteristic of TCCV-1 or TCCV-2.

Polynucleotides

Although nucleotide sequences which encode TCCV-1 or TCCV-2 and its variants are preferably capable of hybridizing to the nucleotide sequence of the naturally occurring TCCV-1 or TCCV-2 under appropriately selected conditions of stringency, it may be advantageous to produce nucleotide sequence encoding TCCV-1 or TCCV-2 or its derivatives possessing a substantially different codon usage, e.g., inclusion of non-naturally occurring codons. Codons may be selected to increase the rate at which expression of the peptide occurs in a particular prokaryotic or eukaryotic host in accordance with the frequency with which particular codons are utilized by the host. Other reasons for substantially altering the nucleotide sequence encoding TCCV-1 or TCCV-2 and its derivatives without altering the encoded amino acid include the production of RNA transcripts having more desirable properties, such as greater half-life or stability for improved translation, than transcripts produced from the naturally occurring sequence.

Also encompassed by the invention are polynucleotides that are capable of hybridizing to the claimed polynucleotide sequences, and, in particular, to those shown in SEQ ID NOs:1 and 3, under various conditions of stringency. (See, e.g., Wahl, G. M. and S. L. Berger (1987) *Methods Enzymol.* 152:399-401; Kimmel, A. R. (1987) *Methods Enzymol.* 152:507-511.) For example, stringent salt concentration will ordinarily be less than about 750 mM NaCl and 75 mM trisodium citrate, preferably less than about 500 mM NaCl and 50 mM trisodium citrate, and more preferably less than about 250 mM NaCl and 25 mM trisodium citrate. Low stringency hybridization can be obtained in the absence of

organic solvent, e.g., formamide, while high stringency hybridization can be obtained in the presence of at least about 35% formamide, and more preferably at least about 50% formamide. Stringent temperature conditions will ordinarily include temperatures of at least about 30° C., preferably at least about 37° C., and more preferably 42° C. Varying additional parameters such as hybridization time, the concentration of detergent, e.g., sodium dodecyl sulfate (SDS), and the inclusion or exclusion of carrier DNA, are well known to those skilled in the art. Various levels of stringency are accomplished by combining these various conditions as needed. In a preferred embodiment, hybridization will occur at 30° C. in 750 mM NaCl, 75 mM trisodium citrate, and 1% SDS. In a more preferred embodiment, hybridization will occur at 37° C. in 500 mM NaCl, 50 mM trisodium citrate, 1% SDS, 35% formamide, and 100 µg/ml denatured salmon sperm DNA (ssDNA). In a more preferred embodiment, hybridization will occur at 42° C. in 250 mM NaCl, 25 mM trisodium citrate, 1% SDS, 50% formamide, and 200 µg/ml denatured ssDNA. Useful variations of these conditions will be readily apparent to those skilled in the art.

The washing steps which follow hybridization can also vary in stringency. Wash stringency conditions can be defined by salt concentration and by temperature. As above, wash stringency can be increased by decreasing salt concentration or by increasing temperature. For example, stringent salt concentration for the wash steps will preferably be less than about 30 mM NaCl and 3 mM trisodium citrate, and most preferably less than about 15 mM NaCl and 1.5 mM trisodium citrate. Stringent temperature conditions for the wash step will ordinarily include temperature of at least about 25° C., more preferably of at least about 42° C., and most preferably of at least about 68° C. In a preferred embodiment, wash step will occur at 25° C. in 30 mM NaCl, 3 mM trisodium citrate, and 0.1% SDS. In a more preferred embodiment, wash step will occur at 42° C. in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS. In a most preferred embodiment, the wash step will occur at 68° C., in 15 mM NaCl, 1.5 mM trisodium citrate, and 0.1% SDS. Additional variations on these conditions will be readily apparent to those skilled in the art.

In another embodiment, polynucleotide sequences encoding all or part of TCCV-1 or TCCV-2 may be synthesized using chemical methods well known in the art. (See, e.g., Caruthers, M. H. et al. (1980) *Nucl. Acids Res. Symp. Ser.* 7:215-223; Hom, T. et al. (1980) *Nucl. Acids Res. Symp. Ser.* 7:225-232.)

The present invention further covers recombinant polynucleotides and fragments having a DNA sequence identical to or highly homologous to the isolated polynucleotides of TCCV-1 or TCCV-2. In particular, the sequences will often be operably linked to DNA segments which control transcription, translation, and DNA replication. Alternatively, recombinant clones derived from the genomic sequences, e.g., containing introns, will be useful for transgenic and knock-out studies, including transgenic cells, organisms, and knock-out animals, and for gene therapy. (See, e.g., Goodnow (1992) "Transgenic Animals" in Roitt (ed.) *Encyclopedia of Immunology*, Academic Press, San Diego, Calif., pp.1502-1504; Travis (1992) *Science* 254:707-710; Capecchi (1989) *Science* 244:1288-1292; Robertson (ed.) (1987) *Teratocarcinomas and Embryonic Stem Cells: A Practical Approach*, IRL Press, Oxford; Rosenberg (1992) *J. Clinical Oncology* 10:180-199; Hogan, et al. (eds.) (1994) *Manipulating the Mouse Embryo: A Laboratory Manual*, 2nd edition, Cold Spring Harbor Press,

N.Y.; Wei (1997) *Ann. Rev. Pharmacol. Toxicol.* 37:119-141; and Rajewsky, et al. (1996) *J. Clin. Invest.* 98:S51-S53.)

Examples of these techniques include: 1) Insertion of normal or mutant versions of DNA encoding TCCV-1 or TCCV-2 or homologous animal versions of these genes, by microinjection, retroviral infection, or other means well known to those skilled in the art, into appropriate fertilized embryos in order to produce a transgenic animal (see, e.g., Hogan, supra); and 2) homologous recombination (see, e.g., Capecchi, supra; and Zimmer and Gruss (1989) *Nature* 338:150-153) of mutant or normal, human or animal versions of these genes with the native gene locus in transgenic animals to alter the regulation of expression or the structure of TCCV-1 or TCCV-2.

The technique of homologous recombination is well known in the art. It replaces the native gene with the inserted gene and is thus useful for producing an animal that cannot express native receptor but does express, for example, an inserted mutant receptor, which has replaced the native receptor in the animal's genome by recombination, resulting in underexpression of the receptor.

Microinjection adds genes to the genome, but does not remove them, and so is useful for producing an animal which expresses its own and added receptors, resulting in overexpression of the receptor. One means available for producing a transgenic animal, with a mouse as an example, is as follows: Female mice are mated, and the resulting fertilized eggs are dissected out of their oviducts. The eggs are stored in an appropriate medium such as M2 medium (see, e.g., Hogan, supra). DNA or cDNA encoding TCCV-1 or TCCV-2 is purified from an appropriate vector by methods well known in the art. Inducible promoters may be fused with the coding region of the DNA to provide an experimental means to regulate expression of the trans-gene. Alternatively, or in addition, tissue specific regulatory elements may be fused with the coding region to permit tissue-specific expression of the trans-gene. The DNA, in an appropriately buffered solution, is put into a microinjection needle (which may be made from capillary tubing using a pipet puller) and the egg to be injected is put in a depression slide. The needle is inserted into the pronucleus of the egg, and the DNA solution is injected. The injected egg is then transferred into the oviduct of a pseudopregnant mouse (a mouse stimulated by the appropriate hormones to maintain pregnancy but which is not actually pregnant), where it proceeds to the uterus, implants, and develops to term. As noted above, microinjection is not the only method for inserting DNA into the egg cell, and is used here only for exemplary purposes.

Since the normal action of receptor-specific drugs is to activate or to inhibit the receptor, the transgenic animal model systems described above are useful for testing the biological activity of drugs directed against TCCV-1 or TCCV-2 even before such drugs become available. These animal model systems are useful for predicting or evaluating possible therapeutic applications of drugs which activate or inhibit TCCV-1 or TCCV-2 by inducing or inhibiting expression of the native or trans-gene and thus increasing or decreasing expression of normal or mutant TCCV-1 or TCCV-2 in the living animal. Thus, a model system is produced in which the biological activity of drugs directed against TCCV-1 or TCCV-2 are evaluated before such drugs become available.

The transgenic animals which over- or underproduce TCCV-1 or TCCV-2 indicate, by their physiological state, whether over- or underproduction of TCCV-1 or TCCV-2 is

therapeutically useful. It is therefore useful to evaluate drug action based on the transgenic model system. One use is based on the fact that it is well known in the art that a drug such as an antidepressant acts by blocking neurotransmitter uptake, and thereby increases the amount of neurotransmitter in the synaptic cleft. The physiological result of this action is to stimulate the production of less receptor by the affected cells, leading eventually to underexpression. Therefore, an animal which underexpresses receptor is useful as a test system to investigate whether the actions of such drugs which result in under expression are in fact therapeutic. Another use is that if overexpression is found to lead to abnormalities, then a drug which down-regulates or acts as an antagonist to TCCV-1 or TCCV-2 is indicated as worth developing, and if a promising therapeutic application is uncovered by these animal model systems, activation or inhibition of TCCV-1 or TCCV-2 is achieved therapeutically either by producing agonist or antagonist drugs directed against TCCV-1 or TCCV-2 or by any method which increases or decreases the expression of TCCV-1 or TCCV-2 in man.

Polypeptides

The predicted sequence of TCCV-1 and TCCV-2 amino acid sequence is shown in SEQ ID NO:2 and SEQ ID NO:4, respectively. The peptide sequences allow preparation of peptides to generate antibodies to recognize such segments, and various different methods may be used to prepare such peptides. As used herein TCCV-1 or TCCV-2 shall encompass, when used in a protein context, a protein having an amino acid sequence shown in Table 2, or a significant fragment of such a protein. It also refers to a vertebrate, e.g., mammal, including human, derived polypeptide which exhibits similar biological function, e.g., antigenic, or interacts with TCCV-1 or TCCV-2 specific binding components, e.g., specific antibodies.

The term polypeptide, as used herein, includes a significant fragment or segment, and encompasses a stretch of amino acid residues of at least about 8 amino acids, generally at least 10 amino acids, more generally at least 12 amino acids, often at least 14 amino acids, more often at least 16 amino acids, typically at least 18 amino acids, more typically at least 20 amino acids, usually at least 22 amino acids, more usually at least 24 amino acids, preferably at least 26 amino acids, more preferably at least 28 amino acids, and, in particularly preferred embodiments, at least about 30 or more amino acids. The segments may have lengths of at least 37, 45, 53, 61, 70, 80, 90, etc., and often will encompass a plurality of such matching sequences. The specific ends of such a segment will be at any combinations within the protein. Preferably the fragment will encompass structural domains, e.g., [Give specific fragments], or unique regions useful in generation of binding compositions with specificity for TCCV-1 or TCCV-2.

In another embodiment of the invention, natural, modified, or recombinant nucleic acid sequences encoding TCCV-1 or TCCV-2 may be ligated to a heterologous sequence to encode a fusion protein. For example, to screen peptide libraries for inhibitors of TCCV-1 or TCCV-2 activity, it may be useful to encode a chimeric TCCV-1 or TCCV-2 protein that can be recognized by a commercially available antibody. A fusion protein may also be engineered to contain a cleavage site located between the TCCV-1 or TCCV-2 encoding sequence and the heterologous protein sequence, so that TCCV-1 or TCCV-2 may be cleaved and purified away from the heterologous moiety.

The protein may be produced using chemical methods to synthesize the amino acid sequence of TCCV-1 or TCCV-2,

or a fragment thereof. For example, peptide synthesis can be performed using various solid-phase techniques. (See, e.g., Roberge, J. Y. et al. (1995) *Science* 269:202-204.) Automated synthesis may be achieved, for example, using the ABI 431 A peptide synthesizer (Perkin Elmer).

The newly synthesized peptide may be substantially purified by preparative high performance liquid chromatography. (See, e.g., Creighton, T. (1983) *Proteins, Structures and Molecular Principles*, WH Freeman and Co., New York, N.Y.) The composition of the synthetic peptides may be confirmed by amino acid analysis or sequencing (e.g., the Edman degradation procedure; Creighton, supra.) Additionally, the amino acid sequence of TCCV-1 or TCCV-2, or any part thereof, may be altered during direct synthesis and/or combined using chemical methods with sequences from other proteins, or any part thereof, to produce a variant polypeptide.

In order to express a biologically active TCCV-1 or TCCV-2, the nucleotide sequences encoding TCCV-1 or TCCV-2 or functional equivalents, may be inserted into appropriate expression vector, i.e., a vector which contains the necessary elements for the transcription and translation of the inserted coding sequence. Methods which are well known to those skilled in the art may be used to construct expression vectors containing sequences encoding TCCV-1 or TCCV-2 and appropriate transcriptional and translational control elements. These methods include in vitro recombinant DNA techniques, synthetic techniques, and in vivo genetic recombination. (See, e.g., Sambrook, J. et al. (1989) *Molecular Cloning, A Laboratory Manual*, Cold Spring Harbor Press, Plainview, N.Y.; and Ausubel, F. M. et al. (1989) *Current Protocols in Molecular Biology*, John Wiley & Sons, New York, N.Y.)

A variety of expression vector/host systems may be utilized to contain and express sequences encoding TCCV-1 or TCCV-2. These include, but are not limited to, microorganisms such as bacteria transformed with recombinant bacteriophage, plasmid, or cosmid DNA expression vectors; yeast transformed with yeast expression vectors; insect cell systems infected with virus expression vectors (e.g., baculovirus) or with bacterial expression vectors (e.g., Ti or pBR322 plasmids); or animal cell systems. The invention is not limited by the host cell employed.

The "control elements" or "regulatory sequences" are those non-translated regions of the vector, e.g., enhancers, promoters, 5' and 3' untranslated regions, which interact with host cellular proteins to carry out transcription and translation. Such elements may vary in their strength and specificity. Depending on the vector system and host utilized, any number of suitable transcription and translation elements, including constitutive and inducible promoters, may be used. For example, when cloning in bacterial systems, inducible promoters such as the hybrid lacZ promoter of the BLUESCRIPT phagemid (Stratagene, LaJolla, Calif.) or PSPORT1 plasmid (Gibco BRL) and the like may be used. The baculovirus polyhedrin promoter may be used in insect cells. Promoters or enhancers derived from the genomes of plant cells (e.g., heat shock, RUBISCO; and storage protein genes) or from plant viruses (e.g., viral promoters or leader sequences) may be cloned into the vector. In mammalian cell systems, promoters from mammalian genes or from mammalian viruses are preferable. If it is necessary to generate a cell line that contains multiple copies of the sequence encoding TCCV-1 or TCCV-2, vectors based on SV40 or EBV may be used with an appropriate selectable marker.

In bacterial systems, a number of expression vectors may be selected depending upon the use intended for TCCV-1 or

TCCV-2. For example, when large quantities of TCCV-1 or TCCV-2 are needed for the induction of antibodies, vectors which direct high level expression of fusion proteins that are readily purified may be used. Such vectors include, but are not limited to, the multifunctional *E. coli* cloning and expression vectors such as the BLUESCRIPT phagemid (Stratagene), in which the sequence encoding TCCV-1 or TCCV-2 may be ligated into the vector in frame with sequences for the amino-terminal Met and the subsequent 7 residues of β -galactosidase so that a hybrid protein is produced; pIN vectors (Van Heeke, G. and S. M. Schuster (1989) *J. Biol. Chem.* 264:5503-5509); and the like. PGEX vectors (Promega, Madison, Wis.) may also be used to express foreign polypeptides as fusion proteins with glutathione S-transferase (GST). In general, such fusion proteins are soluble and can easily be purified from lysed cells by adsorption to glutathione-agarose beads followed by elution in the presence of free glutathione. Proteins made in such systems may be designed to include heparin, thrombin, or factor XA protease cleavage sites so that the cloned polypeptide of interest can be released from the GST moiety at will.

In the yeast, *Saccharomyces cerevisiae*, a number of vectors containing constitutive or inducible promoters such as alpha factor, alcohol oxidase, and PGH may be used. (See, e.g., Ausubel et al., supra; and Grant et al. (1987) *Methods Enzymol.* 153:516-544.)

An insect system may also be used to express TCCV-1 or TCCV-2. For example, in one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes in *Spodoptera frugiperda* cells or in *Trichoplusia larvae*. The sequences encoding TCCV-1 or TCCV-2 may be cloned into a non-essential region of the virus, such as the polyhedrin gene, and placed under control of the polyhedrin promoter. Successful insertion of TCCV-1 or TCCV-2 will render the polyhedrin gene inactive and produce recombinant virus lacking coat protein. The recombinant viruses may then be used to infect, for example, *S. frugiperda* cells or *Trichoplusia larvae* in which TCCV-1 or TCCV-2 may be expressed (Engelhard, E. K. et al. (1994) *Proc. Natl. Acad. Sci.* 91:3224-3227).

In mammalian host cells, a number of viral-based expression systems may be utilized. In cases where an adenovirus is used as an expression vector, sequences encoding TCCV-1 or TCCV-2 may be ligated into an adenovirus transcription/translation complex consisting of the late promoter and tripartite leader sequence. Insertion in a non-essential E1 or E3 region of the viral genome may be used to obtain a viable virus which is capable of expressing TCCV-1 or TCCV-2 in infected host cells (Logan, J. and Shenk, T. (1984) *Proc. Natl. Acad. Sci.* 81:3655-3659). In addition, transcription enhancers, such as the Rous sarcoma virus (RSV) enhancer, may be used to increase expression in mammalian host cells.

Human artificial chromosomes (HACs) may also be employed to deliver larger fragments of DNA than can be contained and expressed in a plasmid. HACs of 6 to 10M are constructed and delivered via conventional delivery methods (liposomes, polycationic amino polymers, or vesicles) for therapeutic purposes.

Specific initiation signals may also be used to achieve more efficient translation of sequences encoding TCCV-1 or TCCV-2. Such signals include the ATG initiation codon and adjacent sequences. In cases where sequences encoding TCCV-1 or TCCV-2, its initiation codon, and upstream sequences are inserted into the appropriate expression vector, no additional transcriptional or translational control signals may be needed. However, in cases where only

coding sequence, or a fragment thereof, is inserted, exogenous translational control signals including the ATG initiation codon should be provided. Furthermore, the initiation codon should be in the correct reading frame to ensure translation of the entire insert. Exogenous translational elements and initiation codons may be of various origins, both natural and synthetic. The efficiency of expression may be enhanced by the inclusion of enhancers which are appropriate for the particular cell system which is used, such as those described in the literature (Scharf, D. et al. (1994) *Results Probl. Cell Differ.* 20:125-162).

In addition, a host cell strain may be chosen for its ability to modulate the expression of the inserted sequences or to process the expressed protein in the desired fashion. Such modifications of the polypeptide include, but are not limited to, acetylation, carboxylation, glycosylation, phosphorylation, lipidation, and acylation. Post-translational processing which cleaves a "prepro" form of the protein may also be used to facilitate correct insertion, folding and/or function. Different host cells which have specific cellular machinery and characteristic mechanisms for post-translational activities (e.g., CHO, HeLa, MDCK, HEK293, and WI38), are available from the American Type Culture Collection (ATCC; Bethesda, Md.) and may be chosen to ensure the correct modification and processing of the foreign protein.

For long-term, high-yield production of recombinant proteins, stable expression is preferred. For example, cell lines, which stably express TCCV-1 or TCCV-2, may be transformed using expression vectors which may contain viral origins of replication and/or endogenous expression elements and a selectable marker gene on the same or on a separate vector. Following the introduction of the vector, cells may be allowed to grow for 1-2 days in an enriched media before they are switched to selective media. The purpose of the selectable marker is to confer resistance to selection, and its presence allows growth and recovery of cells which successfully express the introduced sequences. Resistant clones of stably transformed cells may be proliferated using tissue culture techniques appropriate to the cell type.

Any number of selection systems may be used to recover transformed cell lines. These include, but are not limited to, the herpes simplex virus thymidine kinase (Wigler, M. et al. (1977) *Cell* 11:223-32) and adenine phosphoribosyltransferase (Lowy, I. et al. (1980) *Cell* 22:817-23) genes which can be employed in tk⁻ or aprt⁻ cells, respectively. Also, antimetabolite, antibiotic or herbicide resistance can be used as the basis for selection; for example, dhfr which confers resistance to methotrexate (Wigler, M. et al. (1980) *Proc. Natl. Acad. Sci.* 77:3567-70); npt, which confers resistance to the aminoglycosides neomycin and G-418 (Colbere-Garapin, F. et al (1981) *J. Mol. Biol.* 150:1-14). Additional selectable genes have been described, for example, trpB, which allows cells to utilize indole in place of tryptophan, or hisD, which allows cells to utilize histinol in place of histidine (Hartman, S. C. and R. C. Mulligan (1988) *Proc. Natl. Acad. Sci.* 85:8047-51). Recently, the use of visible markers has gained popularity with such markers as anthocyanins, beta-glucuronidase and its substrate GUS, and luciferase and its substrate luciferin, being widely used not only to identify transformants, but also to quantify the amount of transient or stable protein expression attributable to a specific vector system (Rhodes, Calif. et al. (1995) *Methods Mol. Biol.* 55:121-131).

Antibodies

Antibodies to TCCV-1 or TCCV-2 may be generated using methods that are well known in the art. Such antibod-

ies may include, but are not limited to, polyclonal, monoclonal, chimeric, single chain, Fab fragments, and fragments produced by a Fab expression library. Neutralizing antibodies, (i.e., those which inhibit dimer formation) are especially preferred for therapeutic use.

For the production of antibodies, various hosts including goats, rabbits, rats, mice, humans, and others, may be immunized by injection with TCCV-1 or TCCV-2 or any fragment or oligopeptide thereof which has immunogenic properties. Depending on the host species, various adjuvants may be used to increase immunological response. Such adjuvants include, but are not limited to, Freund's, mineral gels such as aluminum hydroxide, and surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanin, and dinitrophenol. Among adjuvants used in humans, BCG (bacilli Calmette-Guerin) and *Corynebacterium parvum* are especially preferable.

It is preferred that the oligopeptides, peptides, or fragments used to induce antibodies to TCCV-1 or TCCV-2 have an amino acid sequence consisting of at least five amino acids and more preferably at least 10 amino acids, and most preferably at least 15 amino acids. It is also preferable that they are identical to a portion of the amino acid sequence of the natural protein, and they may contain the entire amino acid sequence of a small, naturally occurring molecule. Short stretches of TCCV-1 or TCCV-2 amino acids may be fused with those of another protein such as keyhole limpet hemocyanin and antibody produced against the chimeric molecule.

Monoclonal antibodies to TCCV-1 or TCCV-2 may be prepared using any technique which provides for the production of antibody molecules by continuous cell lines in culture. These include, but are not limited to, the hybridoma technique, the human B-cell hybridoma technique, and the EBV-hybridoma technique (Kohler, G. et al. (1975) *Nature* 256:495-497; Kozbor, D. et al. (1985) *J. Immunol. Methods* 81:31-42; Cote, R. J. et al. (1983) *Proc. Natl. Acad. Sci.* 80:2026-2030; Cole, S. P. et al. (1984) *Mol. Cell Biol.* 62:109-120).

In addition, techniques developed for the production of "chimeric antibodies", the splicing of mouse antibody genes to human antibody genes to obtain a molecule with appropriate antigen specificity and biological activity can be used (Morrison, S. L. et al. (1984) *Proc. Natl. Acad. Sci.* 81:6851-6855; Neuberger, M. S. et al. (1984) *Nature* 312:604-608; Takeda, S. et al. (1985) *Nature* 314:452-454). Alternatively, techniques described for the production of single chain antibodies may be adapted, using methods known in the art, to produce TCCV-1 or TCCV-2-specific single chain antibodies. Antibodies with related specificity, but of distinct idiotype composition, may be generated by chain shuffling from random combinatorial immunoglobulin libraries (Burton D. R. (1991) *Proc. Natl. Acad. Sci.* 88:11120-3).

Antibodies may also be produced by inducing in vivo production in the lymphocyte population or by screening immunoglobulin libraries or panels of highly specific binding reagents as disclosed in the literature (Orlandi, R. et al. (1989) *Proc. Natl. Acad. Sci.* 86: 3833-3837; Winter, G. et al. (1991) *Nature* 349:293-299).

Antibody fragments which contain specific binding sites for TCCV-1 or TCCV-2 may also be generated. For example, such fragments include, but are not limited to, the F(ab')₂ fragments which can be produced by pepsin digestion of the antibody molecule and the Fab fragments which can be generated by reducing the disulfide bridges of the

F(ab')₂ fragments. Alternatively, Fab expression libraries may be constructed to allow rapid and easy identification of monoclonal Fab fragments with the desired specificity (Huse, W. D. et al. (1989) *Science* 254:1275-1281).

Various immunoassays may be used for screening to identify antibodies having the desired specificity. Numerous protocols for competitive binding or immunoradiometric assays using either polyclonal or monoclonal antibodies with established specificities are well known in the art. Such immunoassays typically involve the measurement of complex formation between TCCV-1 or TCCV-2 and its specific antibody. A two-site, monoclonal-based immunoassay utilizing monoclonal antibodies reactive to two non-interfering TCCV-1 or TCCV-2 epitopes is preferred, but a competitive binding assay may also be employed (Maddox, supra).

The present invention provides various methods for determining whether a compound can modulate the activity of TCCV-1 or TCCV-2. The compound can be a substantially pure compound of synthetic origin combined in an aqueous medium, or the compound can be a naturally occurring material such that the assay medium is an extract of biological origin, such as, for example, a plant, animal, or microbial cell extract. The methods essentially entail contacting TCCV-1 or TCCV-2 or fragments thereof, with the compound under suitable conditions and subsequently determining if the compound modulates the activity of TCCV-1 or TCCV-2. The compounds of interest can function as agonists or antagonists of TCCV-1 or TCCV-2 activity. TCCV-1 or TCCV-2 or fragments thereof, can be expressed on a cell or tissue, naturally or recombinantly, or immobilized by attachment to a solid substrate, e.g., nitrocellulose or nylon membrane, glass, beads, etc. An example of a compound that may block a T-type calcium channel is ethosuximide and analogs thereof.

Transcription based assays that identify signals that modulate the activity of cell surface proteins, e.g., receptors, ion channels, etc., may be used to screen candidate compounds for their ability to stimulate reporter gene product expression and their potential to stimulate the expression of TCCV-1 or TCCV-2.

One method for identifying compounds that stimulate TCCV-1 or TCCV-2 promoter-controlled reporter gene expression comprises introducing into a cell a DNA construct that comprises TCCV-1 or TCCV-2 promoter operably linked to a reporter gene, mixing a test compound with the cell and measuring the level of expression of reporter gene product. A change in the level of expression of the reporter gene product indicates that the compound is capable of modulating the level of TCCV-1 or TCCV-2 expression. The reporter gene construct is preferably stably integrated into the chromosomal DNA of the cell, but is also functional for the purposes disclosed herein in the form of an extrachromosomal element. The cell may be a eukaryotic cell, or any cell that contains the elements needed to express a structural gene under the regulatory influence of a mammalian gene promoter.

Other transcription-based assays are well known in the art. (See, e.g., Zlokam, et al. (1998) *Science* 279:84-88; Silverman, supra; and Gonzalez and Negulescu, (1998) *Curr. Opin. Biotechnol.* 9:624-631.) These transcription based assays assess the intracellular transduction of an extracellular signal using recombinant cells that are modified by introduction of a reporter gene under the control of a regulatable promoter.

A two-hybrid system-based approach can also be employed for compound screening, small molecule

identification, and drug discovery. The underlying premise of the two-hybrid system, originally described in yeast by Fields and Song (1989) *Nature* 340:245-246, provides a connection between a productive protein-protein or protein-compound interaction pair of interest and a measurable phenotypic change in yeast. A reporter cassette containing an up-stream activation sequence which is recognized by a DNA binding domain, is operationally linked to a reporter gene, which when expressed under the correct conditions will generate a phenotypic change. The original two-hybrid system has recently been modified for applicability in high-throughput compound screening. (See, e.g., Ho et al. (1996) *Nature* 382:822-826; Licita and Liu (1996) *Proc. Natl. Acad. Sci. USA* 93:12817-12821; and Young et al. (1998) *Nature Biotech.* 16:946-950.)

Assays for identifying compounds that modulate ion channel activity are practiced by measuring the ion channel activity when a cell expressing the ion channel of interest, or fragments thereof, is exposed to a solution containing the test compound and a ion channel selective ion and comparing the measured ion channel activity to the native ion channel activity of the same cell or a substantially identical control cell in a solution not containing the test compound. Methods for practicing such assays are known to those of skill in the art. (See, e.g., Mishina et al. (1985) *Nature* 313:364-369; and Noda, et al. *Nature* 322:836-828.)

Ion channel activity can be measured by methods such as electrophysiology (two electrode voltage clamp or single electrode whole cell patch clamp), guanidinium ion flux assays, toxin-binding assays, and Fluorometric Imaging Plate Reader (FLIPR) assays. (See, e.g., Sullivan, et al. (1999) *Methods Mol. Biol.* 114:125-133; Siegel and Isacoff (1997) *Neuron* 19:1-20; and Lopatin, et al. (1998) *Trends Pharmacol. Sci.* 19:395-398.) An "inhibitor" is defined generally as a compound, at a given concentration, that results in greater than 50% decrease in ion channel activity, preferably greater than 70% decrease in ion channel activity, more preferably greater than 90% decrease in ion channel activity.

The binding or interaction of the compound with a receptor or fragments thereof, can be measured directly by using radioactively labeled compound of interest (see, e.g., Wainscott et al. (1993) *Mol. Pharmacol.* 43:419-426; and Loric, et al. (1992) *FEBS Lett.* 312:203-207) or by the second messenger effect resulting from the interaction or binding of the candidate compound. (See, e.g., Lazareno and Birdsall (1993) *Br. J. Pharmacol.* 109:1120-1127.) Modulation in receptor signaling can be measured using a detectable assay, e.g., the FLIPR assay. (See, e.g., Coward, P. (1999) *Anal. Biochem.* 270:242-248; Sittampalam, supra; and Gonzalez and Negulescu, supra.) Activation of certain receptors, in particular, GPCRs, can be measured an ³⁵S-GTPγS binding assay. (See, e.g., Lazareno (1999) *Methods Mol. Biol.* 106:231-245.)

Alternatively, the candidate compounds can be subjected to competition screening assays, in which a known ligand, preferably labeled with an analytically detectable reagent, most preferably radioactivity, is introduced with the drug to be tested and the capacity of the compound to inhibit or enhance the binding of the labeled ligand is measured. Compounds are screened for their increased affinity and selectivity for the specific receptor or fragments thereof.

Candidate compounds are useful in the treatment or prophylaxis of pain, including, but not limited to, peripheral pain; peripheral neuropathies; pain caused by trauma or toxic compounds; diabetic neuropathy; cancer pain, and the like.

The polynucleotides of the present invention can be used to design antisense oligonucleotides that inhibit translation of mRNA encoding the TCCV-1 or TCCV-2 of the present invention. Synthetic oligonucleotides, or other antisense chemical structures are designed to bind to mRNA encoding TCCV-1 or TCCV-2 and inhibit translation of mRNA and are useful to inhibit expression of TCCV-1 or TCCV-2. This invention provides a means to alter levels of expression of TCCV-1 or TCCV-2 by the use of a synthetic antisense oligonucleotide (SAO) which inhibits translation of mRNA encoding these receptors.

The SAO is designed to be capable of passing through cell membranes in order to enter the cytoplasm of the cell by virtue of physical and chemical properties of the SAO which render it capable of passing through cell membranes (e.g. by designing small, hydrophobic SAO chemical structures) or by virtue of specific transport systems in the cell which recognize and transport the SAO into the cell. In addition, the SAO can be designed for administration only to certain selected cell populations by targeting the SAO to be recognized by specific cellular uptake mechanisms which binds and takes up the SAO only within certain selected cell populations. For example, the SAO may be designed to bind to TCCV-1 or TCCV-2 which are found only in certain cell types.

The SAO is also designed to recognize and selectively bind to the target mRNA sequence, which may correspond to a sequence contained within the sequences of SEQ ID NO:1 or 3 by virtue of complementary base pairing to the mRNA. Finally, the SAO is designed to inactivate the target mRNA sequence by any of three mechanisms: 1) binding to the target mRNA and thus inducing degradation of the mRNA by intrinsic cellular mechanisms such as RNase H digestion; 2) inhibiting translation of the mRNA target by interfering with the binding of translation-regulating factors or of ribosomes; or 3) inclusion of other chemical structures, such as ribozyme sequences or reactive chemical groups, which either degrade or chemically modify the target mRNA.

Synthetic antisense oligonucleotide drugs have been shown to be capable of the properties described above when directed against mRNA targets. (See, e.g., Cohen (1989) *Trends in Pharm. Sci.* 10:435; and Weintraub (1990) *Sci. Am.* 262:40-46.) In addition, coupling of ribozymes to antisense oligonucleotides is a promising strategy for inactivating target mRNA. (See, e.g., Sarver et al. (1990) *Science* 247:1222.)

Diagnostics and kits

The present invention contemplates use TCCV-1 or TCCV-2 polynucleotides, polypeptides, and antibodies in a variety of diagnostic methods kits. Typically the kit will have a compartment containing either a defined TCCV-1 or TCCV-2 polypeptide, polynucleotide, or a reagent which recognizes one or the other, e.g., antigen fragments or antibodies. Additionally the kit will include the reagents needed to carry out the assay in a separate compartment as well as instructions for use and proper disposal.

A variety of protocols including ELISA, RIA, and FACS for measuring TCCV-1 or TCCV-2 are known in the art and provide a basis for diagnosing altered or abnormal levels of TCCV-1 or TCCV-2 expression. Normal or standard values for TCCV-1 or TCCV-2 expression are established by combining body fluids or cell extracts taken from normal mammalian subjects, preferably human, with antibody to TCCV-1 or TCCV-2 under conditions suitable for complex formation. The amount of standard complex formation may be quantified by various methods, but preferably by

photometric, means. Quantities of TCCV-1 or TCCV-2 expressed in control and disease samples from biopsied tissues are compared with the standard values. Deviation between standard and subject values establishes the parameters for diagnosing disease.

In another embodiment of the invention, the polynucleotides encoding TCCV-1 or TCCV-2 may be used for diagnostic purposes. The polynucleotides which may be used include oligonucleotide sequences, complementary RNA and DNA molecules, and PNAs. The polynucleotides may be used to detect and quantitate gene expression in biopsied tissues in which expression of TCCV-1 or TCCV-2 may be correlated with disease. The diagnostic assay may be used to distinguish between absence, presence, and excess expression of TCCV-1 or TCCV-2, and to monitor regulation of TCCV-1 or TCCV-2 levels during therapeutic intervention.

In one aspect, hybridization with PCR probes which are capable of detecting polynucleotide sequences, including genomic sequences, encoding TCCV-1 or TCCV-2 or closely related molecules, may be used to identify nucleic acid sequences which encode TCCV-1 or TCCV-2. The specificity of the probe, whether it is made from a highly specific region, e.g., 10 unique nucleotides in the 5' regulatory region, or a less specific region, e.g., especially in the 3' coding region, and the stringency of the hybridization or amplification (maximal, high, intermediate, or low) will determine whether the probe identifies only naturally occurring sequences encoding TCCV-1 or TCCV-2, alleles, or related sequences.

Probes may also be used for the detection of related sequences, and should preferably contain at least 50% of the nucleotides from any of the TCCV-1 or TCCV-2 encoding sequences. The hybridization probes of the subject invention may be DNA or RNA and derived from the nucleotide sequence of SEQ ID NOs:1 or 3 or from genomic sequence including promoter, enhancer elements, and introns of the naturally occurring TCCV-1 or TCCV-2.

Means for producing specific hybridization probes for DNAs encoding TCCV-1 or TCCV-2 include the cloning of nucleic acid sequences encoding TCCV-1 or TCCV-2 or TCCV-1 or TCCV-2 derivatives into vectors for the production of mRNA probes. Such vectors are known in the art, commercially available, and may be used to synthesize RNA probes in vitro by means of the addition of the appropriate RNA polymerases and the appropriate labeled nucleotides. Hybridization probes may be labeled by a variety of reporter groups, for example, radionuclides such as ^{32}P or ^{35}S , or enzymatic labels, such as alkaline phosphatase coupled to the probe via avidin/biotin coupling systems, and the like.

Polynucleotide sequences encoding TCCV-1 or TCCV-2 may be used for the diagnosis of diseases, conditions, or disorders which are associated with expression of TCCV-1 or TCCV-2 including, but not limited to, pain; peripheral pain; peripheral neuropathies; pain caused by trauma or toxic compounds; diabetic neuropathy; cancer pain, and the like.

In order to provide a basis for the diagnosis of disease associated with expression of TCCV-1 or TCCV-2, a normal or standard profile for expression is established. This may be accomplished by combining body fluids or cell extracts taken from normal subjects, either animal or human, with a polynucleotide sequence, or a fragment thereof, which encodes TCCV-1 or TCCV-2, under conditions suitable for hybridization or amplification. Standard hybridization may be quantified by comparing the values obtained from normal subjects with those from an experiment where a known

amount of a substantially purified polynucleotide is used. Standard values obtained from normal samples may be compared with values obtained from samples from subjects who are symptomatic for disease. Deviation between standard and subject values is used to establish the presence of disease.

Once a disease is established and a treatment protocol is initiated, hybridization assays may be repeated on a regular basis to evaluate whether the level of expression in the subject begins to approximate that which is observed in the normal subject. The results obtained from successive assays may be used to show the efficacy of treatment over a period ranging from several hours to several days to several months.

Additional diagnostic uses for oligonucleotides designed from the sequences encoding TCCV-1 or TCCV-2 may involve the use of PCR. Such oligomers may be chemically synthesized, generated enzymatically, or produced in vitro. Oligomers will preferably consist of two nucleotide sequences, one with sense orientation (5' to 3') and another with antisense (3' to 5'), employed under optimized conditions for identification of a specific gene or condition. The same two oligomers, nested sets of oligomers, or even a degenerate pool of oligomers may be employed under less stringent conditions for detection and/or quantitation of closely related DNA or RNA sequences.

Methods which may also be used to quantitate the expression of TCCV-1 or TCCV-2 include radiolabeling or biotinylating nucleotides, coamplification of a control nucleic acid, and standard curves onto which the experimental results are interpolated. (See, e.g., Melby, P. C. et al. (1993) *J. Immunol. Methods*, 159:235-244; and Duplaa, C. et al. (1993) *Anal. Biochem.* 212:229-236.) The speed of quantitation of multiple samples may be accelerated by running the assay in an ELISA format where the oligomer of interest is presented in various dilutions and a spectrophotometric or colorimetric response gives rapid quantitation.

In another embodiment of the invention, the nucleic acid sequences which encode TCCV-1 or TCCV-2 can be used to generate hybridization probes which are useful for mapping the naturally occurring genomic sequence. Fragments of TCCV-1 and TCCV-2 have been used to map these genes to the appropriate mouse and human chromosomes. The sequences may be mapped to a particular chromosome, to a specific region of a chromosome or to artificial chromosome constructions, such as human artificial chromosomes (HACs), yeast artificial chromosomes (YACs), bacterial artificial chromosomes (BACs), bacterial P1 constructions, or single chromosome cDNA libraries. (See, e.g., Price, C. M. (1993) *Blood Rev.* 7:127-134, and Trask, B. J. (1991) *Trends Genet.* 7:149-154.)

Fluorescent in situ hybridization (FISH) may be correlated with other physical chromosome mapping techniques and genetic map data. (See, e.g., Verma et al. (1988) *Human Chromosomes: A Manual of Basic Techniques*, Pergamon Press, New York, N.Y.) Examples of genetic map data can be found in various scientific journals or at Online Mendelian Inheritance in Man (OMIM). Correlation between the location of the gene encoding TCCV-1 or TCCV-2 on a physical chromosomal map and a specific disease, or predisposition to a specific disease, may help delimit the region of DNA associated with that genetic disease. The nucleotide sequences of the subject invention may be used to detect differences in gene sequences between normal, carrier, or affected individuals.

In situ hybridization of chromosomal preparations and physical mapping techniques such as linkage analysis using

established chromosomal markers may be used for extending genetic maps. Often the placement of a gene on the chromosome of another mammalian species, such as mouse, may reveal associated markers even if the number or arm of a particular human chromosome is not known. New sequences can be assigned to chromosomal arms, or parts thereof, by physical mapping. This provides valuable information to investigators searching for disease genes using positional cloning or other gene discovery techniques. Once the disease or syndrome has been crudely localized by genetic linkage to a particular genomic region (see, e.g., Gatti, R. A. et al. (1988) *Nature* 336:577-580), any sequences mapping to that area may represent associated or regulatory genes for further investigation. The nucleotide sequence of the subject invention may also be used to detect differences in the chromosomal location due to translocation, inversion, etc. among normal, carrier, or affected individuals.

All patents, patent applications, and publications mentioned herein, whether supra or infra, are each incorporated by reference in its entirety. The broad scope of this invention is best understood with reference to the following examples, which are not intended to limit the invention to the specific embodiments described below.

EXAMPLES

Some of the standard methods are described or referenced, e.g., in Maniatis et al. (1982) *Molecular Cloning, A Laboratory Manual*, Cold Spring Harbor Laboratory, Cold Spring Harbor Press; Sambrook et al. (1989) *Molecular Cloning: A Laboratory Manual*, (2d ed.), vols. 1-3, CSH Press, N.Y.; or Ausubel et al. (1987 and Supplements) *Current Protocols in Molecular Biology*, Greene/Wiley, New York; Innis et al. (eds.) (1990) *PCR Protocols: A Guide to Methods and Applications* Academic Press, N.Y. Methods for protein purification include such methods as ammonium sulfate precipitation, column chromatography, electrophoresis, centrifugation, crystallization, and others. See, e.g., Ausubel et al. (1987 and periodic supplements); Deutscher (1990) "Guide to Protein Purification" in *Methods in Enzymology*, vol. 182, and other volumes in this series; and manufacturer's literature on use of protein purification products, e.g., Pharmacia, Piscataway, N.J., or Bio-Rad, Richmond, Calif. Combination with recombinant techniques allow fusion to appropriate segments, e.g., to a FLAG sequence or an equivalent which can be fused via a protease-removable sequence. See, e.g., Hochuli (1989) *Chemische Industrie* 12:69-70; Hochuli (1990) "Purification of Recombinant Proteins with Metal Chelate Absorbent" in Sellow (ed.) *Genetic Engineering Principle and Methods* 12:87-98, Plenum Press, N.Y.; and Crowe et al. (1992) *OIAexpress: The High Level Expression & Protein Purification System* QUIAGEN, Inc., Chatsworth, Calif.

Example I

Homology Search of GenBank

Searching of GenBank databases with the human T-type calcium channel subunit α_{1H} sequence (GenBank Accession No. AF051946; and Cribbs et al. (1998) *Circ. Res.* 83:103-109) revealed two genomic clones from human chromosome 22 with extensive homology to α_{1H} . (GenBank Accession Nos. AL022319 and AL008716.) BLAST results showed that these clones represented the same sequence, potentially a novel T-type Calcium channel as the α_{1G} subunit was shown to be localized to human chromosome 17 and α_{1H} to human chromosome 16. Additionally a further

search of GenBank with the rat α_{1G} sequence also revealed less extensive homology to the two clones above, as well as a human chromosome 17 genomic clone (GenBank Accession No. AC004590), which appeared to contain the entire human α_{1G} sequence within 34 exons.

Comparison of the deduced exon structure of α_{1G} with the alignments from the α_{1H} BLAST against GenBank Accession Nos. AL022319 and AL008716 allowed the identification of many potential exons, from approximately the beginning of domain I to the end of domain IV. Due to insufficient homology with α_{1G} or α_{1H} , several exons could not initially be identified, in particular, exons corresponding to the interdomain regions. Similarly, the amino- and carboxyterminal exons could not be initially identified.

Example II

PCR Cloning and Assembly of TCCVs

PCR primers based on GenBank Accession No. AL022319 sequence were designed to clone the region from domain I to domain IV:

Sense 5' GGGCGCCATCAACTTTGACAACATC 3' (SEQ ID NO:6); and

Antisense 5' CTCACGAAGTACAGCGGCGACAC 3' (SEQ ID NO:7)

Optimized reaction conditions to produce the expected 4 kb product, per 50 μ l reaction, were: each primer at 0.2 μ M, 1xADVANTAGE-GC cDNA reaction buffer (Clontech, Palo Alto, Calif.), 0.2mM dNTPs, 1 μ l ADVANTAGE-GC cDNA polymerase (Clontech), 1xGC MELT (Clontech), and 5 μ l MARATHON-READY human brain cDNA (Clontech). Temperature and time parameters were 94°, 1 min; 95°, 10 sec, 68°, 6 min, 42 cycles; 68°, 10 min.

A band at 4 kb was excised from low-melt agarose gel, melted at 65° C. for 5 min, and subsequently ligated into the pCR2.1 TOPO vector (Invitrogen, Mountain View, Calif.) following kit instructions. The ligated vector was transformed into *E. coli* DH5 α competent cells (Life Technologies, Bethesda, Md.) according to the manufacturer's protocol. Two of the resulting clones, KC-1 and KC-4 were fully sequenced.

BLAST comparison of these sequences with the novel human genomic sequences AL022319 and AL008716 revealed the true exon structure for this region of the gene. This sequence was not identical to that predicted by homology with the other channels. Additionally, KC-1 had 4 mutations and KC-4 had 8 mutations relative to the genomic sequences. Of note, none of the apparent mutations in the KC-1 sequence occurred between the unique AvrII and HindIII sites. Compensation for these mutations revealed a continuous reading frame, whose deduced amino acid sequence was homologous to the α_{1G} and α_{1H} amino acid sequences corresponding to exons 6 to 31 of the α_{1G} sequence. Additional homology comparisons revealed that genomic clone AL008716 only contained exons 2 to 25 and genomic clone AL022319 contained, at least, exons 5 to 31.

The sequence for exons 2-7 (using the α_{1G} numbering of exons) was assembled electronically from the genomic sequences and used to BLAST the GenBank databases. A new chromosome 22 genomic clone was found (GenBank Accession No. AL022312), which contained exon 2 near to its 3' end. In cloning exon 1, a comparison of rat α_{1G} and α_{1H} exon 1 amino acid sequences was made, revealing a short region of amino acid homology at the 3' end. The sequence of the last 30 amino acids from α_{1G} exon 1 was used as query in a TFASTA search of the GenBank data-

bases. This search found a match in the new chromosome 22 genomic clone, AL022312, approximately 27 kb in the 5' direction from exon 2. This potential exon 1 had a reading frame containing the matching homology, as well as additional homology, extending to a potential initiating methionine residue. The large potential intron between exons 1 and 2 had atypical splice sites, AT...AC, instead of the usual GT...AG. The first intron of $\alpha 1$ also has a similar atypical splice site. Electronic splicing of exon 1 to the previously identified exons resulted in a sequence with a continuous open reading frame.

PCR primers, described below, were designed to amplify the region from about 190 bp 5' of the likely start codon to about 120 bp 3' of the unique AvrII site:

Sense 5' CTGGGCCCTCAGCTGTTTCGTAATC 3' (SEQ ID NO:8); and

Antisense 5' GCGCTGGTCATAGCTCATCTCCCTA-GAGA 3' (SEQ ID NO:9)

Reaction conditions were the same as above, except 2.5 μ l MARATHON-READY human brain cDNA (Clontech) was used as template in a 25 μ l reaction, but in the absence of GC-MELT (Clontech). PCR reaction conditions were: 95° C., 1 min; 95° C., 10 sec, 68° C., 20 sec, 72° C., 4 min, 42 cycles; 72° C., 7 min. A portion of this reaction was run into a low-melt agarose gel and a band at 3 kb was excised and cloned as described above. Of four isolates sequenced, KZ-2 was found to have only one silent mutation between the 5' end and the AvrII site.

In order to identify the 3' most exons, 16 kb of genomic clone AL022319 sequence, beginning near exon 26, was run on the GENIE gene finder program, (Lawrence Berkeley National Laboratory) which predicted exons 29, 30, 31 as well as four new additional exons following exon 31. The last exon contained a stop codon in the reading frame and appeared to lack additional splice consensus sites. An additional analysis of 10 kb in the 3' direction predicted no additional exons.

PCR primers, as described below, were designed to overlap the KC-1 sequence (about 200 bp 5' of the HindIII site) and to include the coding region of the possible 3' most exon, including about 100 bp of 3' non-coding sequence:

Sense 5' GCGCTTCTTCAAGGACCGATGG 3' (SEQ ID NO:10); and Antisense 5' CCCAGGTGTGGAC-GAAGTATTGCT 3' (SEQ ID NO:11)

Reaction conditions for amplifying the highly GC-rich sequence were the same as above, except 2.5 μ l MARATHON-READY human brain cDNA (Clontech) was used as template in a 25 μ l reaction, including 1xGC-MELT (Clontech). PCR reaction conditions were: 95° C., 1 min; 95° C., 10 sec, 62° C., 20 sec, 72° C., 4 min, 42 cycles; 72° C., 5 min. A portion of this reaction was run into a low-melt agarose gel and a band at 2.1 kb was excised and cloned as above. Sequence analysis of several of these clones revealed the correct exon structure for this region, which was not entirely as predicted, and the presence of alternative 3' splice site usage in some clones, resulting in a 39 bp difference in exon 32. All clones had one or more base-substitution mutations. However, KS-6, containing the short form of exon 32, had only one silent mutation in the 5' half of the gene bounded by the unique HindIII and BamHI sites. KS-18, containing the longer form of exon 32, also had no mutations between HindIII and BamHI, whereas KS-13 was mutation free only from the BamHI site to the 3' end. Thus, two versions of the 3' end region of the gene from the HindIII site to the stop codon, differing only in the exon 32 splice variation, could be assembled from these three clones. All three clones were digested with HindIII and BamHI and

the reaction products run on a low-melt agarose gel. The desired bands were excised from the gel, melted briefly at 65° C., ligated together and transformed into *E. coli* DH5 α competent cells as above. The 0.9 kb fragments from KS-6 and KS-18 were separately ligated to the 5 kb fragment from KS-13 to give isolates LD-1 and LE-1 respectively.

To assemble full-length coding sequences for the two human $\alpha 1$ splice variants, the 3 kb KZ-2 EcoRI-AvrII fragment, the 2 kb KC-1 AvrII-HindIII fragment, either the 2 kb LD-1 or LE-1 HindIII-NotI fragment, and the 5.5 kb pCleo (Promega) mammalian cell expression vector EcoRI-NotI fragment were prepared and ligated together as above. Of the products of these clonings, isolate LF-1 (TCCV-1) contains the full-length short exon 32 form and isolate LG-1 (TCCV-2) contains the full length long exon 32 form of the human $\alpha 1$ subunit.

Example III

Analysis of Splicing Patterns

Patterns of splicing at the 3' end of human and rat $\alpha 1$ subunit genes were investigated by PCR. Primers were designed to amplify the entire region as well as to amplify specific splice products. Primer locations were chosen, in part, to minimize differences in the rat and human sequences, so that a single primer set could be used to amplify from both templates. Primers 6066 and 6831 were designed to amplify the region from exon 31 to 35 containing the rat and human splice variations. (See FIGS. 2A-2C.)

Four forward primers (Primer Numbers 6352, 6344/88, 6495, and 6495/37) were designed from the human DNA sequences to examine specifically splicing at exon 32 and at exon 33 and to be used with reverse primer 6831. As shown in FIGS. 2A-2C, these primers were designed to span the splice sites, so that only one specific product could be amplified for each primer. The human intron sequence was considered in designing these primers to reduce the possibility of amplifying unspliced sequences.

Optimum PCR conditions were established, using plasmid templates containing the long and short forms of exon 32 and the rat and human forms of exon 33, for which the specific PCR product for each primer set was obtained only from the specific template: 94° C., 30 sec; 94° C., 10 sec, 62° C., 15 sec, 68° C., 1 min, 30 cycles; 68° C., 3 min. PCR reaction conditions were as follows: 1xADVANTAGE cDNA PCR reaction buffer (Clontech), 0.2 mM dNTPs, 1xPCRX reagent (Life Technologies), 0.2 μ M each primer, 0.2 μ l 50xADVANTAGE cDNA polymerase mix (Clontech) and 0.5 ng plasmid template in a 20 μ l reaction.

To examine the presence of the various splice products in MARATHON-READY human brain cDNA (Clontech), 2.5 μ l template was used in 25 μ l reactions as above with 0.25 μ l 50xADVANTAGE cDNA polymerase mix (Clontech). Cycling conditions were identical, except that the annealing temperature was 63° C. for 36 or 42 cycles. Similar results were obtained at 36 or 42 cycles. The long form of exon 32 (TCCV-1) was somewhat more abundant (2 to 5 fold) than the short form (TCCV-2). In addition, only the "human" form of exon 33 was found. A PCR product corresponding to the rat $\alpha 1$ subunit was not detected in the human brain cDNA (See FIG. 3).

Example IV

Transfection of TSA201 Cells

TSA201 cells were plated into wells of BIOCOAT poly-D-lysine coated 6 well dishes (Becton-Dickinson, Mountain

View, Calif.) at a density of 3×10^5 cells/well two days prior to transfection or 7.5×10^5 cells/well one day prior to transfection. The medium was either the usual culture medium but without antibiotics, or, in some cases, a special low-calcium medium.

The vectors containing TCCV-1 or TCCV-2 were transfected into TSA201 cells using the LIPOFECTAMINE 2000 (Life Technologies, Bethesda, Md.) transfection kit and accompanying protocols. For each well of transfected cells, 4 μ g of TCCV-1 or TCCV-2 plasmid DNA and 0.8 μ g of pHook-1 DNA were combined in a tube with 250 μ l of OPTI-MEM serum free medium (Life Technologies). An equal volume of diluted LIPOFECTAMINE 2000 reagent was added to each tube of diluted DNA and the mixtures were mixed and allowed to incubate at room temperature in the dark for 20 minutes. During the incubation, the medium on the cells was changed to 2.5 ml/well of DMEM with 0.1 mM MEM non-essential amino acids (Life Technologies), without serum and without antibiotics. The DNA/LIPOFECTAMINE 2000/OPTI-MEM mixture was added dropwise to cell wells while swirling the microtiter plate. The plate was returned to 37° C., 5% CO₂ for 4 to 5 hours.

Cells were resuspended and plated immediately after stopping the transfection reaction. Medium was removed from the cell wells and replaced with 2 ml of Dulbecco's Phosphate Buffered Saline (Life Technologies) without calcium or magnesium. The dish was returned to the incubator for four minutes. Cell monolayers were rinsed from the surface of the wells by trituration with a 2 ml pipet, directing the stream at the surface of the well to dislodge the cells. The resuspended cells were plated at 1:20 dilution in either regular culture medium or low calcium medium in 35 mm dishes that had been pre-coated with poly-D-lysine.

Alternatively, following the 4-5 hour incubation described above, the medium was replaced with either regular culture medium or low calcium medium and the cells were incubated overnight at 37° C. The cells were subsequently resuspended and plated as described above.

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity and understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

What is claimed is:

1. A polynucleotide encoding a polypeptide comprising the amino acid sequence of SEQ ID NO:2 or 4.
2. The polynucleotide of claim 1, wherein the polynucleotide is detectably labeled.
3. An isolated polynucleotide which is the complement of the polynucleotide of claim 1.
4. The isolated polynucleotide of claim 3, wherein the polynucleotide is detectably labeled.
5. The polynucleotide of claim 1, wherein the polynucleotide comprises the nucleic acid sequence of SEQ ID NOS:1 or 3.
6. An expression vector comprising the polynucleotide of claim 1.
7. A host cell comprising the expression vector of claim 6.
8. The host cell of claim 7, wherein the host cell is a prokaryotic cell.
9. The host cell of claim 7, wherein the host cell is a eukaryotic cell.

10. A method of producing an TCCV-1 or TCCV-2 polypeptide, the method comprising:

- a) culturing the host cell of claim 7 under conditions suitable for expression of the polypeptide; and
- b) recovering the polypeptide from the host cell.

11. A method of detecting a polynucleotide encoding an TCCV-1 or TCCV-2 polypeptide in a sample containing nucleic acid material, the method comprising:

- a) contacting the sample with the polynucleotide of claim 3 under conditions suitable for formation of a hybridization complex; and
- b) detecting the complex, wherein the presence of the complex is indicative of the presence of the polynucleotide encoding the polypeptide in the sample.

12. A test kit comprising a polynucleotide of claim 5.
